Food in Developing Countries

Vienna, 24 - 27 February 1969

PROTEIN ENRICHMENT OF FOOD IN DEVELOPING COUNTRIES <sup>1/</sup>

by

W. Heimann

<sup>1/</sup> The views and opinions expressed in this paper are those of the author and do not necessarily reflect the views of the secretariat of UNIDO. This document has been reproduced without formal editing.

We regret that some of the pages in the microfiche copy of this report may not be up to the proper legibility standards, even though the best possible copy was used for preparing the master fiche.

Those who look at the world's food imbalance of today and tomorrow, generally agree that the most important aspect of the world's food shortage is the lack of protein in the diets of the poor and developing countries.

The malnutrition in protein or the deficiency in protein of high biological value concerns mainly some countries in Asia, Africa, as well as the regions in South- and Central America. A discussion of protein nutrition is outside the scope and space of this paper but some short references may be given.

The minimum protein requirement is estimated to be approximately 1.0 gms per kg of body weight of an adult human, this will say 60 - 70 gms daily; in the growing child the minimum requirement for optimum growth may be more than 2 gms per kg of body weight. At least a third of the total protein should be of animal source.

TABLE 1  
Staple Foods and Nutritive Value <sup>1/</sup>

	Calories		Consumption of			Protein gms/day	
	Require- ment/day	Actual Supply	Cereals kg/year	Tubers and Roots	Carbo- hydrate Calo- ries	Total	Ani- mal Pro- tein
North Africa	2260	97	148	18	75	66	16
West- and Central Africa	2360	103	93	320	74	50	1
East- and South Africa	2380	101	149	36	73	69	17
South Asia	1970	65	139	10	70	50	7
Central America	2130	90	112	11	71	58	14
Australia and New Zealand	3250	125	82	53	48	94	62
U.S.A.	3110	120	67	49	40	93	66
West Europe	2910	113	111	101	55	83	39

In Table 1, one can recognize the basic diet (staple food) of the different areas in respect of the protein uptake. It can be seen from this table that especially in the regions of West and Central Africa the main diet of the people consists of roots and tubers (e.g. Cassava and Yams), therefore, the protein uptake is insufficient. In South Asia too a deplorable situation of protein deficiency has existed for a long time.

The consequences are mostly found among the poorer population, because foods richer in protein, like meat, eggs, milk, are too expensive, or not at all available. They are compelled to cover their food requirements almost, if not only, by their native starch-containing cereals, legumes, roots and tubers, which are much cheaper.

But very often the economical situation is not the only reason for protein deficiency, for it is found also where protein is available in sufficient amounts. The cause of this malnutrition is to be sought in ignorance.

Now allow me to reduce the protein problem to the simplest origins. This introduction and consideration may also help to study more easily the local protein situation and give a better ability to improve protein deficiency.

Human beings are in contrary to plants and many micro-organisms dependent on the supply of protein or certain fragments of proteins in the food. These fragments are the amino acids. Today we know about 25 amino acids as basic units of food protein. A certain number of it can be synthesised and converted by our organism. But food must absolutely contain the so-called essential amino acids in a certain minimum amount - 8 for adults, 10 for children.

Table 2 see next page

TABLE 2  
Essential Amino Acids

L-Lysine

L-Leucine

L-Isoleucine

L-Valine

L-Methionine

L-Threonine

L-Tryptophane

L-Phenylalanine

The biological value of the different kinds of proteins is determined by the contents of these essential amino acids.

Potato	60	85	70	71
Navy bean	50	50	42	47
Peas	60	70	60	44
Sweet potato	80	85	75	72
Spinach	70	100	90	-
Cassava	20	50	40	-

- (a) Calculated by comparing the quantity of each essential amino acid per g of total nitrogen with that of the same amino acid in the 1957 FAO reference pattern.
- (b) Calculated by comparing the quantity of each essential amino acid per g of total essential amino acids, including tyrosine and cystine, with that of the same amino acid in whole egg.
- (c) Calculated by comparing the quantity of each essential amino acid per g of total essential amino acid, including tyrosine and cystine, with that of the same amino acid in human milk.
- (d) Sulfur-containing essential amino acids (methionine plus cystine).

Table 3 shows that animal protein is dietetically more valuable than plant protein, e.g. cereal and legume protein. Striking appears the low protein content of Cassava (~ 1.8 per cent). In countries like West and Central Africa the tubers of Cassava, Yams, as well as roots serve as basic diet; there is no deficiency in calories per se. But the low protein content of the tubers and the poor quality of these proteins effect a quantitative and qualitative protein deficiency. For this reason a quantitative protein enrichment of this basic diet is indispensable.

What is the reason that protein of cereals and legumes is not highly valuable (see Table 4)? Today one knows, that these proteins lack certain essential amino acids. Table 4 shows a composition of the limiting essential amino acids in the most important varieties of cereals.

TABLE 4  
Limiting Amino Acids in Cereals

Cereal Variety	Limiting Amino Acid No. 1	Limiting Amino Acid No. 2
Wheat (10 - 12 per cent protein)	lysine	threonine
Rice (8 per cent)	lysine	threonine
Maize (9 per cent)	lysine	tryptophane
Millet (10 per cent)	lysine	threonine
Sorghum (10 per cent)	lysine	threonine
Barley (10 per cent)	lysine	threonine

Protein of legumes is characterized by a small contents of methionine. Since in many technical developing countries sufficient amounts of cereals and legumes are available - 70 per cent of the cultivated ground of the earth is used for cereals - the quantitative protein supply is covered there. <sup>1/</sup> This is valid even in case of nutrition with rice, which shows the lowest protein content. The protein supply respectively protein intake

covers in case of the above mentioned consumption of rice the daily intake of 1 gm protein per 1 kg of body weight, recommended by FAO. The most acute deficiency in those countries is that in high quality protein! In many regions, there are sufficient quantities of cereal protein, but because of its lack of essential amino acids, it is insufficient in quality. This means, its biological value is low. To be of high quality, this protein requires supplementation with the missing essential amino acids which means to enrich the actual protein. It would be unrealistic to produce more animal protein in the developing countries in order to cover the protein deficiency: The production of satisfactory animal protein in developing countries is an uneconomical process which does not pay because of high loss of transformation by animal feeding.

Other means have to be found to raise protein quality in those countries. Nowadays in principle there are just two possibilities:

1. Enrichment of basic diet as cereals or legumes with pure amino acids,
2. Enrichment of staple foods containing proteins with special supplementary value,
  - (a) with animal foods,
  - (b) with plant foods.

#### I. ENRICHMENT WITH AMINO ACIDS 4/

As pointed out, the nutritive value of a dietary protein depends on the pattern or proportions and quantity of essential amino acids which are furnished together with the above protein to the body after absorption by the intestine.

The term "enrichment of protein" will say: protein containing food of lower quality should be revalued, which means to bring it in condition of better "biological protein value". This method has been used in the U.S.A. for many years to enrich feeding-protein with amino acids for poultry nutrition. In order to improve its protein value, methionine is added to legumes which serve as the protein source.

In any case, the way, the know-how, the method and the money for reaching this aim for human nutrition should be adapted to the nutrition and nutrition habits of the concerning developing country.

This means for the practical use: the only success promising method at present, which can guarantee a quick and safe possibility to improve the situation of nutrition with protein containing food of high value is: enriching specifically the staple foods (mostly rich in carbohydrates) with the lacking essential foodstuffs, in this case with protein units.

The staple foods of the concerning country are to be chosen as the basis. The means we must add depend on it. The way of adding, that means the technology of enrichment, can differ and depends on several factors.

In many countries the cereals - as corn, rice, wheat, sorghum - are still the main staple foods. As you know, the protein is not complete in biological nutritive sense. The limiting amino acids are lysine and threonine. Corn has still a second limiting amino acid: Tryptophane. These amino acids should be added to cereals in order to improve their protein value.

Theoretical calculations have shown that it would be possible to double the biological value of wheat protein by adding 0.4 gms lysine and 0.3 gms threonine to 100 gms wheat. Within a wheat production of 100 million tons per year, 25 millions of tons of proteins could be saved. This is as much as the total world production of animal protein.

In countries where legumes are the staple food, the amino acid methionine has to be added to the legumes as to peas, soya, peanuts.

It is important to point out that an addition of amino acids as enriching agents only is nutritively effective if the quantitative protein content of the food is sufficient.

There exists the danger of a destruction of the whole protein metabolism in adding pure amino acids in high quantities; which means that also within an optimal protein supply the utilization of the other amino acids is diminished. This situation or this phenomenon is well known as amino acid imbalance.

The chemical analysis gives the first view in determining the optimal amounts of the enriching amino acids in order to avoid amino acid imbalance. The real relations can only be found by biological tests (growth test), alone by this analytical methods the physiological factors - such as digestion and resorption - can be involved.

Here, two examples of this problem: The supplementation of bread protein by the amino acid lysine shows Table 5.

TABLE 5  
Growth of Weanling Male Rats on 90 % Bread  
Diet Supplemented with Graded Levels of Lysine  
(five-week growth data) by ROSENBERG

At first the biological value is growing with increasing quantities of the added lysine; but from a definite additive amount no further increase of the biological value can be achieved.

Table 6 gives the results of feeding tests with lysine enriched rice.

**TABLE 6**  
**Growth of Weanling Male Rats on Processed**  
**Rice Diet Supplemented with Graded Levels**  
**of Lysine (No Biotin added)**

6

Here with higher levels of the supplementary lysine a lowering in growth occurs: amino acid imbalance.

Also in the next table (No. 7) you can see in comparing peanut protein, that the addition of lysine and threonine gives a lower protein efficiency ratio (PER) than without these amino acids. Both of these amino acids are in optimal amounts in the natural peanut protein.

**TABLE 7**  
**EFFICIENCY OF PEANUT PROTEIN**  
(Growth and Protein Content of Rats)

Essential amino acids	L-lysine	L-threonine	mg/g casein	PER <sup>1</sup>
-	-	-	30	1.10
-	0.4	-	30	1.10
-	-	0.1	30	1.10
-	0.4	0.1	30	1.10
0.1	0.4	0.1	30	1.10

PER = Protein Efficiency Ratio

1) PER = Protein Efficiency Ratio =  $\frac{\text{mg/g protein}}{\text{mg/g protein casein}}$

Therefore, an addition of these amino acids is an added amino acid substance, e.g. in a lower protein efficiency. If you add the necessary amino acid substances, you will receive a considerable increase of PER.

Table 7 (page 11) gives results by PER and al.  $\checkmark$  and essential amino acid content. Case is compared with lysine and threonine, along with lysine and threonine.

I want to show you in Table 8 that the addition of both essential amino acids results in a higher improvement in PER than the only addition of the first essential amino acid lysine alone. However, the lysine is the correct and first amino acid added to all animals.

### Production of Amino Acids

Now come notice on the production of the amino acids we need for the fortification of cereals and legumes.

Tables 9 and 10 show two ways to win L-lysine by chemical synthesis  $\frac{1}{2}$ . In Japan, lysine as well as methionine are synthesized by fermentation  $\frac{1}{2}$ .

### Technology of Fortifying with Amino Acids

As a matter of fact in developing countries, cereals and other foods rich in carbohydrates, represent the main staple food. From the point of view of nutrition and with a view to a certain kind of technique of the protein enrichment, they are considered to be the basis of the protein carriers. The technique of protein enrichment of cereal products can be made by different methods. The method of enrichment has to be adapted to the respective kind of cereal and its state. Whether wheat or rice grains, its milling products (flour) or protein concentrates have to be improved.

### Methods of Fortifying, Using either Cereal Grains or Processed Cereal Products

The pure nutrients like amino acids are added at very low levels and have therefore no effect on any organoleptic (sensoric) properties of the processed cereal product.

When cereals are milled into flour or flakes or processed to certain concentrates, the enrichment can be carried out by either on a batch basis or on a continuous basis using suitable feeders and mixers. There are in general very simple ways of proceeding, using the same simple methods exercised for a long time for vitamin enrichment  $\frac{1}{2}$ .

But enrichment techniques become more difficult when the cereal is consumed in whole grain. This concerns particularly the regions where rice represents the main staple food (basic diet), because of the almost universal custom of washing the

Table 9: Chemical Synthesis of L-Lysine (Basic Material: Caprolactam)

Table 10: Chemical synthesis of L-Lysine (Basic Material Cyclohexanone)

Five grams before adding or by adding the grams in an excess quantity of water like to surface particles of dust. In these cases and extremely sensitive case traces of the solid matter which (like grease or oil) are usually, and the suspended ingredients (like dust) are protected with water-soluble materials in form of the suspended grain handling which can be used in the case termed with process concentration.

There are naturally some limitations of intelligent handling as applied to the foregoing description. Method (2) has given a number of examples for some practical processing in intelligent methods in making grease with suspended particles. Concentration by heating the whole grease with the powder, emulsifying and drying and also by incorporating the particles in the form of suspended grains. Grease and other grease will have been added to suspending and drying techniques, although the addition of the water and liquid by suspended grain handling makes a better approach.

Limitations of the process distribution of particles in suspending conditions in the requirements of various industries and so on for the process distribution operations, these cases are of process with conditions which be added and used by suitable methods.

A great deal would be given to these parts of the world population, which is to be made, and that shows, the range that extends to a large extent from various and the products that in various cases, some to produce a good result. The use of these particles toward from various operations of grease and their primary forms, by adding the stability and their contents of particles in the liquid phase. These are the various cases, that it is possible that can be made the suspension of the particles of a solid phase which should be made. These cases of the particles which have been made in some of the process which increase from, the particles, emulsions and other cases. But it is important to remember that the range of suspended

This shows that animal proteins in suitable mixing ratios result in a significant increase of the biological value of plant proteins.

The enrichment of the cereal and legumes staple foods with animal protein is, of course, only possible if these animal foods are available.

As you know, an increasing production of animal protein in the technically underdeveloped countries is not possible because of the high transformation loss by feeding animals. Nevertheless, it is a wonderful enrichment of the basic cereal and legume foods with animal proteins such as milk powder. Several products have been developed on this basis in different countries with the help of national and international organizations as FAO. Here a list of these products: See page 19 and 20, Table 12.

The problem of this enrichment is the need of milk powder in developing countries, but it can either not be produced at all, or only in insufficient quantities. These are also the reasons for the fortification with eggs and fish products (fish, dried fish or fish meal).

Therefore, it is necessary to find out ways and means of enriching plant staple foods in these developing countries with protein rich indigenous plant foods.

(b) Enrichment with Plant Protein Foods

The problem here is not only increase of the agricultural production of the usually grown crops but it also involves the necessity for the

- (1) Identification of new edible vegetable materials which contain essential amino acids suitable for proper supplementation of the low quality proteins of many common food crops.

**TABLE 12**  
**Protein Food Mixtures <sup>11/</sup>**

- (ii) To realize the possibility of their production in various regions.
- (iii) To find the proper and not too complicated technological methods of processing to render them as edible foods with an acceptance as desired by the native people.

I will try to show you that this way will be possible to verify at least in some important examples and technological possibilities.

To solve this problem, we must at first know the protein composition of the different plant foods. Much work has been done so far in this field, but certainly there is still much left to be done.

But if our aim is to simplify the problem on the amino acid contents of the plant proteins we find some differences (see Table 4). You remember that cereals contain as first limiting amino acid lysine, while legumes have as limiting amino acid methionine. By adding legumes to cereals, a better protein value must be reached. Research work shows results. As you see in Table 13, a mixture of about 40 per cent beans with 60 per cent of corn gives a protein value comparable to the height of egg protein.

TABLE 13  
Minimum Requirement of Different Protein Mixtures 10/

It is interesting, that in Guatemala the poor people take this proportion of beans and corn for their usual diet.

In all countries where cereals and legumes as beans and peas are cultivated, the development of food or rather the education of people to such food mixtures which contain both staple foods, beans as well as corn in a similar proportion, will help to improve the qualitative protein lack.

Feeding experiments with children in Tanzania with a mixture of 1/3 beans and 2/3 corn showed an effective improvement of health.

In Algeria a weaning product was developed on the basis composition from wheat, chick-peas, lentils (name: Aliment de Sauvage, see page 11, Table 12).

Industrially and economically important for enriching cereals are the oil seeds, mainly peanut, soybean, cotton seed. Here are some examples of such mixtures developed in several countries (the complete composition with all ingredients such as vitamins or milk is not given here).

**TABLE 14**  
**Food Mixtures of Cereals and Oil Seeds**

Cereal Staple Food	Enriching Oilseed	Name of Product	Country
Corn	+ cotton seed flour	Incaparina	Guatemala
Corn	+ cotton seed flour + defatted soybean flour	Incaparina	Colombia
Corn	+ defatted soybean flour	Incaparina	Mexico
Corn	+ defatted soybean flour	Fortifex	Brazil
Corn	+ peanut soybean	Provelo	South Africa
Corn pre-cooked	+ defatted soybean flour	OMI	U.S.A.
Corn degerminated + wheat	+ defatted soybean	Coplagge	U.S.A.
Wheat (milled)	+ defatted oilseed flour	Mil-Ahar	India
Barley flour	+ peanut flour	Las-Pano	India
Millet flour	+ peanut flour	Aliment de Sauvage	Senegal

On the basis of the above information, the following information is being furnished to you for your information and for the use of your organization and the interested parties.

**Table 1**

The long-term contract and arrangements with these products are being furnished to you for your information and for the use of your organization and the interested parties.

**Development of Inocparina** <sup>12/</sup>

It is interesting to follow the development of such a new product; let us show this with the example of Inocparina.

This is the first vegetable-rich food product came out after ten years of intensive laboratory research and five years of commercial development in several Latin American countries. Inocparina is the name given by INIA to vegetable mixtures containing 25 per cent or more of protein, comparable in quality to those of animal origin. The use has been proved suitable for the feeding of young children as well as for adults. Several formulae, utilizing vegetable protein concentrates derived from cottonseed or soybeans, have been developed and are now in commercial production in several countries. The next table shows the basic Inocparina formulae especially in commercial applications.

**TABLE 10**

**Basic Formulae and Alternative Substitutions**  
of Inocparina <sup>12/</sup>

Formulae			
Inocparina 500 g	So. 10	So. 14	So. 15
Ground cereal

Subsistence Flour	30		19
Wheat Flour		30	19
Wheat germ	3	3	3
Salt	1	1	1
Vitamins A, I, B.	650	650	650

\* Other sources of rice, corn or sorghum, or other available cereal grains (ground or unground), may be varied and used separately or together to reach a total of 60 g or 65 g of the total product.

This kind of protein-rich food product is utilized in the home in accordance with the cultural pattern of the consumers. It may be readily incorporated in such foods as soups, cookies, drinks, etc. Its principal use in Latin America has been as a popular drink commonly called "Atole".

The biological evaluation and clinical testing with animals and children have proved that the protein content and quality of the mixture approach those of milk!

The following data (Table 17) compare the nutrient content of one glass of Incaparina with that of other common foods:

**TABLE 17**

**Notes:** Values taken from the Food Composition Table for Central America and Panama, Fourth Edition (FAO Publication E-240).

\* One glass of atole is prepared by dissolving either 25 g of Incaparina or corn masa in one glass of water, boiling the mixture for 10 to 15 minutes and sweetening it with 12 g of sugar.

Although this product primarily was developed for preventive purposes and has been used to cure serious cases of protein malnutrition, it is not a medicine. It is a food!

Formula modification (see Table 14) like in this protein-rich product T1, are possible for many other protein-rich food products and gives promise for the adaptation of further new products to the dietary patterns of other areas of the developing countries where such a protein supplement is needed. This example represents the result of the efforts to develop suitable protein-rich food mixtures since 1952 at the Institute of Nutrition for Central America and Panama (INCAP) based on maize, cottonseed flour, sorghum and some Torula Yeast + vitamin A as the only ingredients that may have to be imported ✓.

The increase in sales as the result of the wide acceptance of this type of protein-rich food contains a graphic representation from 1963 to 1965:

### Block Diagram of Control System

### TABLE Description of the [unclear] in [unclear]

**Plant Protein Concentrate**

is a very important source of protein and protein concentrate  
for many ruminating animals such as ruminants the **protein**  
concentrate contains essential amino acids instead of the oil  
components it is possible to produce an oil-free protein concentrate  
of protein content containing approximately 80 per cent of dry matter  
and 20 per cent of protein concentrate. Protein concentrate manufacturing  
has to start at the start, the extraction of oil from protein, however,  
is not as good as that of soybeans. Protein concentrate is obtained  
primarily by the extraction of oil from soybeans and lupines, but it is  
possible to extract oil from lupines for the extraction of the **protein**  
concentrate (and lupines) - but we give an example of the possible use

The protein efficiency ratio (PER) of a feed supplement for  
calves was 1.14 and that of the same supplement with **protein**  
concentrate was 1.11 for all protein. Thus the fortified  
protein feed was manufactured at the 20 per cent level in a soybean  
protein form and for to allow more, the feed was as effective as  
at approximately 80 per cent of the feed in promoting growth.

The reference is particularly relevant to supplement the water-  
soluble protein found in the regions of Central Africa, e.g.  
by protein concentrate manufacturing.

Protein concentrate, containing 20 per cent of protein, is a  
dry protein product; it is commercially manufactured (in U.S.A.)  
and may find other use in feeds.

**Protein** - It is possible to extract the oil from the protein by  
means of organic solvents (or by extraction of the residual  
oil) and to extract the oil residue or extract the protein  
and the protein is a concentrate to its preparation.  
The various technical steps used in separating protein from  
oilseed extracted protein are similar to those of protein  
preparation of soy beans.

1. Preparation of a water-moal mixture and addition of protein dissolving chemicals such as caustic with following extraction with alkali.
2. The protein fraction was prepared by means of screening, filtration and/or centrifuging.
3. The clarified extract is treated with acid (as coagulating chemical) to precipitate the protein as cheese-like curd from water-protein-solution.
4. Separation of the protein curd from the solution, dewatering, washing and drying.

Possibly the most extensive use of peanuts as a food for most people all over the world, especially for developing countries, is in the form of protein. In India much emphasis is put on peanut flour and peanut protein isolates because of the need in high protein foods in that country. Unfortunately those countries where peanuts are most abundant are able to utilize the method of preparation of peanut protein only in a limited way. But the technical way of preparing peanut protein and protein products, described above, is simple and uncomplicated, that there should be given any technical help in producing peanut protein as a food for developing countries.

Recently it has been possible during processing of oil seeds to win protein as well as oil by impulse rendering and to separate oil and protein fractions continuously in a one-way-process. This represents a remarkable progress in oil and protein technology.

#### Cottonseed Concentrates

Cottonseed represents another important source utilized for human consumption, but the development of cottonseed protein concentrates encountered a number of difficulties. In particular the presence of a toxic (phenolic) pigment, called gossypol which is found throughout the plant. By suitable defatting and dehulling

softened and by treating it to remove (or reduce) the contents of this toxic factor germinal to a suitable level (ratio), it is possible now to produce a blend product containing 5% per cent or more of protein.

However, there are some technical difficulties yet to overcome the low contents of germinal. By carefully designed oil extraction processing conditions using special oil seed extracts, we can obtain an edible softened protein concentrate having a protein contents of about 30 per cent and a moisture of germinal of 0.05 per cent of the mass. It presents the same technical difficulties in processing of softened is, to reduce the contents of germinal without any destruction of the nutritive value of the softened protein obtained. It is hoped to secure a satisfactory protein concentrate of sufficiently high quality by employing the new procedure solvent extraction process in near future, which gives of high nutritive value (PDI) and free of germinal.

Considering the advantages and possibilities of the worldwide use of oil seeds as actual and potential protein sources, we should not overlook a serious problem in connection with oil seeds and oil seed products in the tropics. The affliction these are a mycotoxin produced by a fungus which grows rapidly on im- properly harvested and stored oil seeds and kernel oil products in the tropics by practical progress and action of this problem will have to be applied applications concerning the nutrition of the developing countries in the tropics.

A main problem in respect to produce protein concentrates from oil seeds - free of aflatoxin - is to provide means of preventing the contamination of the crop with fungi or to eliminate the aflatoxin from the processed products.

Nevertheless, reference should be given to the utilization of oil seed products of all. It needs the continuous encouragement

of various materials and their properties for use in practice. The  
 results of these investigations, as shown in the preceding pages, are  
 very interesting and have a bearing on the design of  
 structures. It is hoped that the results of these investigations will  
 be of some value and assistance in the design of structures.

References

 American Society of Civil Engineers*, Vol. 1, 1904, pp. 15-24.  
 3. "The strength of concrete in shear," *Proceedings of the  
 American Society of Civil Engineers*, Vol. 1, 1904, pp. 25-34.

The work herein shows that the strength of concrete in  
 tension is very low and that the strength of concrete in  
 shear is also very low. It is suggested that if  
 these results are confirmed, the design of structures  
 should be based on the assumption that the strength of  
 concrete in tension and shear is very low.

Material	Strength
Concrete	1000
Steel	20000
Wood	10000
Brick	1000
Cast Iron	10000
Aluminum	10000
Copper	10000
Lead	10000
Gold	10000
Silver	10000
Iron	10000
Steel	20000

Cast Iron	10000
Aluminum	10000
Copper	10000
Lead	10000
Gold	10000
Silver	10000
Iron	10000

It is suggested that if these results are confirmed, the design of structures  
 should be based on the assumption that the strength of concrete in  
 tension and shear is very low.

The suggested system is responsible for the of actual pro-  
cess. The technical staff should be able to the best systems  
is responsible for design. But there are other factors to  
which business systems management from having to work  
with different. During the last 12 years, business systems  
have been almost gone and are being to restore the former  
difficulties.

The need for design should have a clear understanding of the  
production of last process management.

It can be seen that the principles of working and the applied  
business systems are not very different from those to design  
of last process. Some aspects of technical systems can be used by  
both of methods. The business systems are the same as those of  
technical last process.

**INTERNATIONAL ECONOMIC DEVELOPMENT**

**Introduction**

Since 1945, there has been an increase of attention to certain underdeveloped areas of the world. This is due to the fact that the world is now producing more goods than it can consume. These surplus goods must be sold in some way, and this has led to the development of new markets for these surplus goods.

**1945**

Immediately after 1945, there was the interest of various countries in the world, the U.S. and elsewhere. To take an interesting example, production of steel has been attempted, and this has had some effects in Japan.

**International Development**

Since development activity is carried by various means and is subject to the structure of production by various countries, it is possible to have different results from these activities. These various programs of international development are now being carried on around the world.
