SUMMARY

VINYL CHLORIDE MONOMER ^{1/}

M. Antonin
Pechiney-St.-Gobain
Paris, France

Vinyl chloride monomer is today an industrial raw material of great importance. World production capacity was over 3 million tons per annum in 1967 and has been expanding at an average rate of 15% per annum, which shows that the consumption has by no means reached saturation.

Vinyl chloride has been known since the early days of organic chemistry. It was first prepared in 1835. Its industrial development however is comparatively recent, to more than a century elapsed between the discovery of the product and the beginning of its technical use (1835-1945). While its industrial manufacture from acetylene was worked out in 1912 and the first polymers of vinyl chloride had been

^{1/} The views and opinions expressed in this paper are those of the author and do not necessarily reflect the views of the secretariat of the UNIDO. This document has been reproduced without formal editing.

been improved by the use of ...

Since 1954, these processes have developed rapidly and even faster since
1960. More than 10 original processes are at present available and their uses
have been generally shown by the licensing that is taking place. They vary in
the nature of the catalyst used, a fixed or fluidized bed, by the temperature and
pressure of the reaction and by the quantities of the compound reacting which
may differ according to the importance given to the yield on ethylene or on
hydrochloric acid.

This sort of reaction moreover, allows us to integrate the production of

vinyl chloride with that of chlorination solvents. The ESO process is an example of this type of integration as it allows to produce practically all the grades of the chlorinated products from ethylene.

224000

Back round (1. 1. 1)

Vinyl chloride is not a new product, but it is, when regarded, from the development of the plastics, one of the most important. It is found, not only in the form of vinyl chloride itself, but also concerning its use, for the development of vinyl chloride is closely connected with that of acetylene. Vinyl chloride is a gas, which is used, in the industrial development of the plastics, about 1.5 million tons per year. This is a common knowledge, but it is a fact, that in the world, there is no firm, which produces it in a large quantity, and available, for the market, in a form, which is sufficiently convenient for use in the industry, vinyl chloride, nor even, has little application in the industry, which is why its development has taken place mainly in the domain of the plastic materials, and it will be a task for the future, to find a way, to use it in a larger quantity, vinyl chloride is a gas, which is not suitable for use in the form of a liquid, and, therefore, all the systems, which have been proposed, and are in use, for the production of this compound are, naturally, very complicated.

The first synthesis of vinyl chloride was carried out by G. M. B. in 1835, in the form of a mixture of C_2H_3Cl with acetylene, which was produced in a reaction in which, acetylene and chlorine were used. It was at that time, when the first synthesis of vinyl chloride was carried out, and it was, in the form of a mixture of C_2H_3Cl with acetylene; as a result, the dichloroethane $C_2H_4Cl_2$ (Dichloroethane) was obtained, which was then treated with chlorine, to produce vinyl chloride.

The first synthesis of vinyl chloride was carried out by G. M. B. in 1835, in the form of a mixture of C_2H_3Cl with acetylene, which was produced in a reaction in which, acetylene and chlorine were used. It was at that time, when the first synthesis of vinyl chloride was carried out, and it was, in the form of a mixture of C_2H_3Cl with acetylene; as a result, the dichloroethane $C_2H_4Cl_2$ (Dichloroethane) was obtained, which was then treated with chlorine, to produce vinyl chloride.

The only industrial reaction, which is used for the production of vinyl chloride, is the reaction of acetylene with chlorine, which is carried out at about 195°C, and is catalyzed, in the presence of nickel, by $SnCl_4$ or $SnCl_2$, at about 195°C. The first industrial process of production of vinyl chloride, which was developed in 1930, in the form of a mixture of C_2H_3Cl with acetylene, was carried out in the laboratory by G. M. B. in 1835.

The first synthesis of vinyl chloride was carried out by G. M. B. in 1835, in the form of a mixture of C_2H_3Cl with acetylene, which was produced in a reaction in which, acetylene and chlorine were used. It was at that time, when the first synthesis of vinyl chloride was carried out, and it was, in the form of a mixture of C_2H_3Cl with acetylene; as a result, the dichloroethane $C_2H_4Cl_2$ (Dichloroethane) was obtained, which was then treated with chlorine, to produce vinyl chloride.

hydrobromic acid.

The first step in the synthesis of the polymer is the reaction of the monomer with hydrogen bromide. The reaction is carried out in a solution of the monomer in a suitable solvent, such as carbon tetrachloride, at a temperature of 0°C. The reaction is exothermic and the heat of reaction is about 10 kcal/mole.

The polymerization of the monomer is carried out in a solution of the monomer in a suitable solvent, such as carbon tetrachloride, at a temperature of 0°C. The reaction is exothermic and the heat of reaction is about 10 kcal/mole. The polymerization is carried out in a solution of the monomer in a suitable solvent, such as carbon tetrachloride, at a temperature of 0°C. The reaction is exothermic and the heat of reaction is about 10 kcal/mole. The polymerization is carried out in a solution of the monomer in a suitable solvent, such as carbon tetrachloride, at a temperature of 0°C. The reaction is exothermic and the heat of reaction is about 10 kcal/mole.

The investigation of the mechanism of the polymerization of the monomer is carried out in a solution of the monomer in a suitable solvent, such as carbon tetrachloride, at a temperature of 0°C. The reaction is exothermic and the heat of reaction is about 10 kcal/mole. The polymerization is carried out in a solution of the monomer in a suitable solvent, such as carbon tetrachloride, at a temperature of 0°C. The reaction is exothermic and the heat of reaction is about 10 kcal/mole.

After the polymerization is complete, the polymer is isolated by precipitation with a large excess of a suitable solvent, such as methanol. The polymer is then dried in a vacuum oven at a temperature of 50°C.

The development of the polymerization process is described in detail in the literature. The polymerization is carried out in a solution of the monomer in a suitable solvent, such as carbon tetrachloride, at a temperature of 0°C. The reaction is exothermic and the heat of reaction is about 10 kcal/mole.

A recent investigation of the mechanism of the polymerization of the monomer is carried out in a solution of the monomer in a suitable solvent, such as carbon tetrachloride, at a temperature of 0°C. The reaction is exothermic and the heat of reaction is about 10 kcal/mole. The polymerization is carried out in a solution of the monomer in a suitable solvent, such as carbon tetrachloride, at a temperature of 0°C. The reaction is exothermic and the heat of reaction is about 10 kcal/mole.

Page 1

The overall reaction is a free-radical process, integrated with that of the polymerization of CH₂=CH₂. The process occurs in a single step, and is reversible.

4. Kinetics of the reaction

The reaction is a free-radical process, and the rate of polymerization is proportional to the square root of the concentration of the initiator. The reaction is reversible, and the rate of polymerization is proportional to the square root of the concentration of the initiator.

discontinued. The very first of these is a new method for the rapid production of a new type of alloy, namely, synthetic.

The discovery of the alloy, which is a new type of alloy, the first of these is a new method for the rapid production of a new type of alloy, namely, synthetic. The second of these is a new method for the rapid production of a new type of alloy, namely, synthetic.

Third, the discovery of a new method for the rapid production of a new type of alloy, namely, synthetic. Fourth, the discovery of a new method for the rapid production of a new type of alloy, namely, synthetic. Fifth, the discovery of a new method for the rapid production of a new type of alloy, namely, synthetic. Sixth, the discovery of a new method for the rapid production of a new type of alloy, namely, synthetic. Seventh, the discovery of a new method for the rapid production of a new type of alloy, namely, synthetic. Eighth, the discovery of a new method for the rapid production of a new type of alloy, namely, synthetic. Ninth, the discovery of a new method for the rapid production of a new type of alloy, namely, synthetic. Tenth, the discovery of a new method for the rapid production of a new type of alloy, namely, synthetic.

These procedures are based on the fact that the reaction which

The results of the above work are given in Table I. It is seen that the
 reaction of the chloroacetyl chloride with the vinyl chloride
 proceeds in a similar manner to that of the chloroacetyl
 chloride with the vinyl chloride. The reaction is
 catalyzed by the presence of a small amount of
 water. The reaction is also catalyzed by the presence
 of a small amount of the chloroacetyl chloride. The
 reaction is also catalyzed by the presence of a small
 amount of the vinyl chloride. The reaction is also
 catalyzed by the presence of a small amount of the
 chloroacetyl chloride. The reaction is also catalyzed
 by the presence of a small amount of the vinyl
 chloride. The reaction is also catalyzed by the
 presence of a small amount of the chloroacetyl
 chloride. The reaction is also catalyzed by the
 presence of a small amount of the vinyl chloride.

The reaction of the chloroacetyl chloride with the
 vinyl chloride is also catalyzed by the presence of
 a small amount of the chloroacetyl chloride.

The reaction of the chloroacetyl chloride with the
 vinyl chloride is also catalyzed by the presence of
 a small amount of the vinyl chloride. The reaction
 is also catalyzed by the presence of a small amount
 of the chloroacetyl chloride. The reaction is also
 catalyzed by the presence of a small amount of the
 vinyl chloride. The reaction is also catalyzed by
 the presence of a small amount of the chloroacetyl
 chloride. The reaction is also catalyzed by the
 presence of a small amount of the vinyl chloride.

The reaction of the chloroacetyl chloride with the
 vinyl chloride is also catalyzed by the presence of
 a small amount of the chloroacetyl chloride. The
 reaction is also catalyzed by the presence of a small
 amount of the vinyl chloride. The reaction is also
 catalyzed by the presence of a small amount of the
 chloroacetyl chloride. The reaction is also catalyzed
 by the presence of a small amount of the vinyl
 chloride. The reaction is also catalyzed by the
 presence of a small amount of the chloroacetyl
 chloride. The reaction is also catalyzed by the
 presence of a small amount of the vinyl chloride.

of hydrochloric acid, which is recovered by condensation of the vapors of vinyl chloride by means of a cooling coil. The process, for example, in the synthesis of vinyl acetate. Chloroacetylene is then converted to acrylonitrile by means of a cooling coil and aqueous solution, and is recovered by means of a cooling coil. The process is similar and the utility of the process is obvious, the catalysts are water soluble and the synthesis of diene-chloride and the synthesis of polymer, in particular, the synthesis of vinyl chloride, is therefore not needed.

This is the third type of process which is described in general procedures, which are of the parallel type, which are the "stage" process, where it is possible to produce the product of vinyl chloride without having to provide the catalyst, without having to provide hydrochloric acid.

Table 5 shows four types of general processes. In the first type ethylene and pure acetylene are added to the reaction mixture with the conventional method and in condensed liquid form. The chlorination of ethylene in the liquid phase is carried out with ethane 1-2 which is purified then polymerized and distilled which, after purification, is ready for polymerization with hydrochloric acid, which is used for the catalytic hydrochlorination of the acetylene. The acetylene chloride that remains is sent for purification, the process is similar to the process in which the acetylene is purified and polymerized.

In the second process, the acetylene and ethylene are added to the reaction mixture, producing a mixture of diene-chloride and hydrochloric acid. I have already given some details of this. The mixture containing dilute acetylene and ethylene is first subjected to the chlorination with HCl produced in the factory itself. The first part of the vinyl chloride formed is separated out, the remaining mixture, containing diene-chloride, is subjected to chlorination to obtain the diene-chloride 1-2 which is purified, polymerized and converted to vinyl chloride. The hydrochloric acid generated in the pyrolysis stage is used in the chlorination stage.

In the third type of integrated process, chlorine is the only raw

chloride ions, and the utilization of the Cl_2 is effected by conversion it into chlorine by the conventional process of $2 HCl \rightarrow H_2 + Cl_2$, which was built in 1955, but which has been operated in the case of the cathodes in a continuous way by the electro-chemical method since 1957. The same is also true in the case of the chlorine production. With the progress of advanced technology and the use of electrolytic cells, the chlorine production has increased from 1955 to 1965 and is expected to increase further. The chlorine production has increased from 1955 to 1965 and is expected to increase further. The chlorine production has increased from 1955 to 1965 and is expected to increase further. The chlorine production has increased from 1955 to 1965 and is expected to increase further.

Similarly, in the case of the chlorine production, the chlorine production has increased from 1955 to 1965 and is expected to increase further. The chlorine production has increased from 1955 to 1965 and is expected to increase further. The chlorine production has increased from 1955 to 1965 and is expected to increase further. The chlorine production has increased from 1955 to 1965 and is expected to increase further. The chlorine production has increased from 1955 to 1965 and is expected to increase further.

The chlorine production has increased from 1955 to 1965 and is expected to increase further. The chlorine production has increased from 1955 to 1965 and is expected to increase further. The chlorine production has increased from 1955 to 1965 and is expected to increase further. The chlorine production has increased from 1955 to 1965 and is expected to increase further. The chlorine production has increased from 1955 to 1965 and is expected to increase further.

4. Different present-day processes for chlorination

The process of chlorination which consists in chlorinating an ethylenic compound, especially ethylene, with a chlorine compound Cl_2 is a mixture of two reactions. The first reaction dates back to 1921, but the second reaction of the present day, gained acceptance towards 1955, the first being due to the fact that in 1921, which built an installation for chlorination of ethylene to dichloroethane 1,2 in a tubular reactor in which the chlorine was in the form of a gas, this chlorine being diluted by a substance, silicon chloride, which is removed, by the reaction of

reduction is generally of 25% to 30%.

The first four processes mentioned in this file saw the light before 1964. The others have come out between 1964 and the present time or are in process of being developed. Some of them are already under licence to other companies. I should like to mention first the MILL process which was an improvement on the old fluid bed, a genuine solid process of carboxylation developed by the silica sand of the American company M.L.L.O. and used in a number of the liquid phase, that is to say, that the styrene is treated in a aqueous solution containing cuprous chloride and is converted to acrylonitrile in these conditions, while the reduced solution, containing cuprous chloride is reoxidized to cupric chloride by K_2O_2 and air in a further stage of the process.
