STANDARDIZATION OF STEEL AND STEEL PRODUCTS TO FACILITATE CO-ORDINATION OF NATIONAL, INTERREGIONAL AND INTERNATIONAL SPECIFICATIONS AND TO PROMOTE TRADE AMONG DIFFERENT COUNTRIES 1/

> by B. S. Krishnamachar, India

SUMMARY

Rapid changes in the political map of the world during the last two decades or so have stimulated significant developments in the economic and industrial life of many countries. Reconstruction programmes undertaken by newly independent nations have underscored the need for developing national resources and meeting their specific requirements in respect of raw materials as well as industrial products. Instead of following the specifications of a few industrially advanced countries, developing nations have set about the task of laying down their own standards at national as well as regional levels. Steel and steel products as key materials of construction and plant and machine building, have naturally received considerable attention in this regard.

The coming into being of a multiplicity of specifications has thus given rise to new problems in the interchange of steel and steel products between nations.

Since its independence in 1957, India too faced this problem. Rapi' industrialization of the country led to the import of technical knowhow, materials and equipment from a number of foreign countries for the establishment of various industries.

* This is a summary of a paper issued under the same title as ID/WG.14/33.

^{1/} The views and opinions expressed in this paper are those of the author and do not necessarily reflect the views of the secretariat of UNIDO. The document is presented as submitted by the author, without re-editing.

ID/WG.14/33 Summary Page 2

In almost all cases, equipment, manufacturing schedules and specifications for raw materials were based on practices followed in the donor country, thus leading to the operation of a host of different specifications for engineering materials. As a consequence, most of the manufacturers were compelled to depend heavily on imported materials for their manufacturing programmes.

To deal with the situation, a programme of rationalization and formulation of specifications for all types of steels including alloy and special steels, was undertaken by the Indian Standards Institution in 1956. The programme resulted in the formulation of the following Indian Standard:

IS: 1570-1961 Schedules for Wrought Steels for General Engineering Purposes

The Standard lists 156 varieties of steel compared to more than 1500 varieties then being used in the country. To achieve further economy, the number of steels has since been reduced to only 86 varieties, thus facilitating creation of indigenous production capability at reduced cost and also easy availability.

As a further aid to the industry, IS: 1871-1962 "Commentary on Indian Standard wrought steels for general engineering purposes" was published with a view to assisting the user to select proper steels for specific purposes. This commentary deals with steels in groups according to their metallurgical behaviour and heat treatment.

Conservation of steel through efficient use of available resources has been achieved through rationalization in the number of steel sections and improvements in their production. Four years of intensive study at ISI as well as by expert committees has resulted in the formulation of Indian Standards on improved and rationalized series of beams, channels, angles, tee bars and bulb angles. All these standards have been based on metric system of measurement.

Member-countries of the European Coal and Steel Community (CECA) have also done similar work by developing a new series of beam sections which are more economical than those earlier rolled in these countries primarily with a view to achieving economy and also competing with other materials of building construction. Similar developments have taken place in the UK and the USSR.

Attempts have also been made to establish regional standards taking into consideration raw materials and techniques available in each region. Standards

ID/WG.14/33 Summary Page 3

now being evolved among the Latin American countries and the efforts that have already been put in by the CECA countries and many of the East-European countries are typical examples of regional standardization.

All these developments underline the need for unifying national and regional specifications so as to facilitate interchangeability and mutual exchange of materials between different countries. Taking note of this imperative need, the International Organization for Standardization, through its Technical Committee ISO/TC 17 - Steel, has been making efforts to formulate recommendations on specifications and methods of tests for steels used in industry. The Committee has so far published 47 Recommendations and more are under preparation. India is trying to adopt these Recommendations as far as possible in preparing her national standards. A similar approach by other countries would go a long way in reducing varieties of steel used in industry, leading to greater collaboration between nations and promotion of international trade.

INTRODUCTION

Intensive programmes of industrial development the world over have given a bigh push to the production of steel and steel products in recent years. World steel production in 1967 approximated 525 million tons, almost double the tonnage produced ten years ago. The types, qualities and shapes of steel and steel products that are produced have also considerably increased during the past several years. A number of countries have already developed standard specifications for steel and steel products, while some others are in the process of doing so to meet their specific requirements.

Standardization and variety reduction of steels and steel products is one of the important methods by which conservation and effective utilization of steel can be made possible. In this article a study of different standards on steels and steel products has been made and the need for co-ordination of the existing national standards at regional and international levels has been stressed.

A general study of the development of specifications current in different countries indicates that industrially advanced countries first developed specifications for steels and these were later adopted by several other countries. For example, the ASTM standards are widely used in Latin American, Middle East and South East countries of Asia. Similarly, the British, German and USSR specifications are also widely used in Middle East, South East and East European countries. The reason for such a trend is obvious. Many of the developing countries have to depend i on other countries for their requirements of steels and perforce adopt the specification of the country concerned. This situation, although logical, has created problems for the developing as well as for the developed countries. For example, in India, a number of industrial units have entered into collaboration with different countries from where such assistance was forthcoming. A survey conducted some time ago indicated that over 1500 varieties of steels were in use in India thus posing innumerable problems both from the point of import and indigenous production. On the other hand, similar problems confront the developed countries in as much as they

ID/WG.14/33 Page 4

have to cater to a variety of specifications for export purposes. In the following paragraphs, it is proposed to deal with these aspects in greater detail.

Standard Specifications for Steels

A review of the work done in India on formulation of standard specifications for steels would enable appreciation of the need for development of regional and international standards.

Rapid industrialization of the country soon after Independence in 1947 ied to the imports of technical know-how, materials and equipment from a number of foreign countries for the establishment of various industries. In almost all cases the equipment manufacturing schedules and the specifications for raw materials were based on the practices followed in the donor country. This led to the operation of a multiplicity of specifications for engineering materials. Furthermore, India had not established an alloy and special steel industry although during the Second World War the manufacture of steels covering practically the entire range from carbon steels to quality aircraft steels and ordnance steels was undertaken in the country. As a consequence, most of the manufacturers were compelled to depend heavily on imported materials for their manufacturing programme.

On the recommendation of the Government, the Indian Standards Institution (ISI) took up in 1956 a programme of rationalization and formulation of specifications for alloy and special steels on a priority basis. A separate technical committee was set up under the Structural and Metals Division of ISI to deal with the subject. As a first step, a detailed questionnaire was issued to all concerned for collecting data regarding the production and use of alloy and special steels in the country. To assist ISI in this work, the services of an expert from UK were made available to the Insitution under the Colombo plan.

A special study group wis constituted to scrutinize in detail the data collected and formulate proposals for rationalization keeping in view the importance of using indigenous raw materials and the conservation of some of the most strategic alloying elements in steel such as nickel and molybdenum

for which India had to depend entirely on imports.

A detailed study of the information thus collected indicated that instead of restricting the scope of work to the rationalization of alloy and special steels only, it would be advantageous to undertake rationalization of all types of steels. Accordingly, co-ordinated statements were prepared indicating Indian and overseas steel specifications then in vogue under the following broad categories:

- a) Steels specified by tensile properties but without detailed chemical composition, and
- b) Steels specified by chemical composition.

These were further sub-divided into:

- 1. Carbon steels,
- 2. Ca_bon and carbon-manganese free cutting steels
- 3. Alloy steels other than stainless and heat resisting steels
- 4. High alloy steels stainless and heat resisting steels, and
- 5. Carbon and alloy tool steels.

In these statements steels of similar chemical and physical properties and end-use were grouped together. After careful scrutiny, the study group recommended certain steels in each group which could meet Indian requirements for all types of machine tools and components. Typical examples of this kind of exercise are illustrated in Annex I (Tables 1 - 6)

On the basis of these recommendations, a document detailing draft Indian Standards Schedules was prepared and circulated to all concerned for eliciting comments. Discussions were held with major steel consuming industries and as a result of these deliberations, IS:1570-1961 Schedules for wrought steels for general engineering purposes, was published. Besides the broad categories mentioned above, an additional schedule for carbon steel wire was also included in this standard at the finalization stage.

Schedule I is applicable to carbon and low alloy steels which are put into service in the hot rolled, normalized or annealed condition in the form of plate, sheet, strip, sections, bars, forgings, and tubes, where the main criterion in

ID/WG.14/33 Page 6

selection and inspection of steel is the tensile property. In this group specific mention may be made of structural steels St 42, St 52 and St 55 which replaced a number of British, American and Indian Railway Specifications then in vogue. The Schedule also covers steel St 63 for tramway and railway axles and St 66 for railway wheels and tyres.

Schedule II is applicable to carbon steels which are to be supplied to a definite chemical composition. In addition to the specified mechanical properties, limits for carbon and manganese are laid down. Keeping in view the requirements of the industry, efforts have been made to strike a balance so that an excessive number of steels is not included in the Schedule. The overlapping of carbon ranges is, however, deliberate so as to allow steel producers greater flexibility in the allocation of the material. Further, since some of the carbon steels are also used in the hardened and tempered condition for certain tensile strengths, a range of 0.6C to 0.90 per cent manganese has been kept for steels C35Mn<u>75</u>, C40, C45, C50 and C55Mn<u>75</u> to ensure satisfactory hardening particularly in heavier sections such as for laminated springs. Rail steel C50Mn1 has also been included in the Schedule. The use of innumerable varieties of carbon steels in terms of British and American specifications has thus been simplified te 27 carbon steels in thic group.

Schedule III is applicable to carbon and carbon-manganese free cutting steels supplied to specified composition. The maximum tonnage of carbon-free cutting steel is supplied to steel 13525 in the country. It corresponds to British EnlA, SAE 1112 and German 15520. Also included in the Schedule are 1.3 to 1.7 manganese free cutting steels to be used in the hardened and temp red condition.

Schedule IV is applicable to alloy steels other than stainless and heat resisting steels supplied to specified composition. The steels covered in this Schedule are silicon, manganese, molybdenum, chromium, chromium-molybdenum (creep resisting) nickel-chromium and nickel-chromium-molybdenum steels. In rationalizing these steels, specific care has been taken to conserve as much nickel and molybdenum as possible and to develop steels using indigenously available alloying elements. For example, chrome steel 40Crl would comply with some of the combinations of tensile strengths and ruling sections for which one per cent chrcmium-molybdenum steel En19 may have to be used, thereby saving molybdenum. Further, manganese-molybdenum steel 35Mn2Mo45 has been included in place of En100 in order to save 0.75 per cent nickel. Another example worth mentioning in this connection is the inclusion of 1.5 per cent nickel-chromium-molybdenum steel 40Ni2Cr1Mo28 which would satisfy some combinations of higher tensile strength and larger ruling sections in place of En30A and En30B with 4.5 per cent nickel. Nickel-chromium-molybdenum steel 2.5 per cent 40Ni3Cr65Mo55 has been included to satisfy the remaining combinations of high nickel steels. Silico-manganese spring steels 37Si2Mn20 and 55Si2Mn90 and chrome-vanadium spring steel 50Cr1V23 are the other important examples of ratio-nalization.

Schedule V is applicable to steels with high alloy content primarily for^o corrosion and heat resisting purposes and which are supplied to specified composition. In this group also rationalization has been attempted keeping in view the conservation of nickel and molybdenum as far as possible without at the same time impairing the properties or creating any difficulty in production.

Schedule VI is applicable to carbon and alloy steels supplied to specified composition. This Schedule covers water hardening steels, oil hardening steels, non-distorting steels, shock resisting steels, hot working steels, die steels, high speed steels and mould steels. In order to determine which of the many British, American and German tool steels should be included in this Schedule, a detailed study was made essentially on the basis of the types of alloys and rationalization was accordingly carried out in this Schedule. Of course, water hardening carbon steels in Schedule II which are suitable for tools of simple designs and small sections have been included in this Schedule. Where exacting conditions of service are encountered, benefits have been derived by the addition of small quantities of vanadium which slightly increases the thoughness and resistance to shock and fatigue and provides a structure of finer grains. Such steels included in the Schedule are used for cold heading dies, blanking dies, hammer pistons and for similar other applications. A small amount of chromium has been added for providing adequate hardening in larger sections and improving wear.

ID/WG.14/33 Page 8

It is to be noted that the number of steels covered in IS:1570-1961 was only 156 compared to more than 1500 varieties being used in the country. The technical committee responsible for the preparation of this standard also felt that the number of steels included could be further reduced after some time when the industry gained experience with regard to the use of alternate steels.

As a further step, work was initiated by major steel consuming industries for rationaliging the use of steel in their field. Here also some encouraging results have been achieved. For example, machine tool industry in the country has been able to rationalize its requirements to one carbon and two low alloy constructional steels.

The Textile Machinery Manufacturers' Association in India studied their requirements of steels as per IS:1570-1961 and some rationalization has been achieved. Similarly, the automobile industry has reduced its requirements to about 28 steels.

To achieve further economy, the number of steels has since been reduced to only 86 varieties.

As a further aid to the industry, IS:1871-1962 Commentary on Indian Standard Schedules for wrought steels for general engineering purposes, has been published with a view to assisting the users to select proper steels for specific purpose. In this Commentary, steels have been discussed in groups according to their metallurgical behaviour and heat treatment. For the benefit of users, some of the typical applications of standard steels have been listed in this Commentary.

Also, a comparison of Indian Standard Specification on steels with overseas standards such as American (SAE, AISI, ASTM, ASM) British, German, Japanese and Russian standards (IS:1870-1965 Comparison of Indian and overseas standards for wrought steels for general engineering purposes) has been published. For ease of reference, steels in this statement have been arranged in the ascending order of maximum carbon content thus bringing together, as far as possible, similar compositions.

In order to facilitate international trade and to co-ordinate various national standards for steel including definitions, specifications and

methods of tests, a technical committee at the international level ISO/TC 17 - Steel, was set up in 1948 with UK as its Secretariat.

Under the main Technical Committee, a number of Working Groups and Subcommittees have been set up to deal with the various subjects under its programme of work.

The Technical Committee ISO/Tc 17 has so far published 47 recommendations and many more are under preparation. India is trying to adopt them as far as possible in preparing her national standards. If similar attempts are made by all the countries, the types of steels used in industry would be greatly reduced, thus leading to greater production at reduced cost and easy availability.

Standard Specifications for Steel Products

<u>Steel Sections</u> - Rationalization in number and improvement in the production of sections have been attempted in practically all major steel producing countries. But, improvements effected in the sections through an analysis of their efficiency properties and their redesign were particularly noticeable in countries where there was severe competition in the home and in the export markets, or where the structural steel industry had to face severe competition from reinforced and pre-stressed concrete.

It would be pertinent to briefly explain the work in India on the subject of standardization in the field of steel sections. India has been experiencing steel scarcity for many years but is became particularly acute after the Second World War. It may be interesting to note that the Indian steel industry achieved its peak production of 1.36 million tons during the War but it came down to about 0.85 million tons in 1948. Production could be stapped up only gradually to about one million tons by 1952 and over 1.5 million tons by 1957. The present production is around 6 million tons.

The need for conservation of steel through efficient use of available resources thus assumed urgent importance for a speedy development of national economy, particularly in the period following India's Independence in 1947. The realization of this fact led the Government to appoint in May 1949, a special committee to examine the problem in detail and to suggest ways and means of conserving available steel. This Committee after careful study suggested:

- a) use of alternate materials to the maximum possible extent,
- b) making improvements in design procedures by improving the existing codes,
- c) increased use of steel of higher performance and rationalization of steel sections, and
- d) promotion of welding in place of riveting.

The recommendations of this Committee were considered by the Planning Commission of the Government of India in December 1950 and the Government was requested to entrust to Indian Standards Institution the responsibility of taking up a Steel Economy Programme involving formulation and implementation of standards relating to production and use of steel.

Many complex problems were involved requiring close study and careful compilation of available data and experience of industrially advanced countries. A critical examination of India's own needs and potentialities was required and answers had to be found to questions of basic engineering importance.

Four years of intensive study at the ISI Directorate General and by the expert committee resulted in the formulation of Indian Standards on improved and rationalized series of beams, channels, angles, tee bars, and bulb angles. For obvious reasons, all these standards have been based on metric system of measurements. In formulating the high efficiency standards, note has been taken of many factors including production standards current in the country at that time, limitations and capabilities of the existing mills and of the new mills being installed, national standards and competitive company standards introduced elsewhere, attempts made in other countries towards improvement of standards for steel sections, efficiency in the utilization of sections in structures and analysis of factors which affect the efficiency and the extent to which it is possible to achieve efficiency in practice under Indian working conditions. The improvements effected in beam and channel sections, towards which efforts were mainly directed, could be summarized as follows:

- 1. reduction in web thickness,
- 2. increase in the width of flanges,
- 3. reduction in the slope of flanges,
- 4. rationalization in the number of sections produced and arrangement of sections in more systematic series, and
- 5. general reduction of weight.

In the case of angles, tee bars, etc., the work has been mostly one of conversion and rationalization of the present production standards to the metric system and additions and deletions of certain sections due to condideration of consumers requirements.

Member Countries of the European Coal and Steel Community (CECA) have also done similar work as India by developing a new series of beam sections which are more economical than those rolled earlier in these countries primarily with a view to achieving economy and also competing with other materials for building construction. This work was initiated around 1948 and completed in 1957.

The United Kingdom also started thinking about developing new sections somewhere around 1957-58 and changed over to the new parallol flange sections around 1960-61. Even at present, beams up to 8 in. having 5° taper flanges are rolled in standard mills. Sections over 8 in. in depth have a 5 per cent slope and are rolled in universal mills or in standard mills with an additional finishing stand. Similar developments have taken place in the USSR resulting in a new series of hot rolled sections which are more economical than those used hitherto in that country. These sections have again been based on scientific approach and after establishing the rolling possibilities in their mills.

Thus, it would be seen that practically every country has attempted development of new sections. Such attempts would naturally bring about a large variety of hot rolled steel sections in the world with the result that interchangeability and mutual exchange of material between different countries would become extremely difficult and quite often impossible.

ID/WG.14/33 Page 12

Annex II (Tables 7 to 12) will illustrate the various types of steel beams, channels and angles commonly used in some of the countries.

Taking note of this wide variety and need to unify and develop efficient steels, a Working Group ISO/TC 17/WG 8 was specially set up under ISO/TC 17 - Steel in 1961. This Working Group has already made considerable headway in formulating recommendations for angles, column sections etc. Work is already under way to formulate draft recommendations for beam and channel sections.

Regional Standards

In addition to the development of national standards in different countries of the world, attempts have also been made to establish regional standards taking into consideration raw materials and the technique available in each region. The standards now being evolved amongst the Latin American Countries and the effort that has already been put in by the CECA countries and many of the East European countries are typical examples of establishing regional standards.

CONCLUSION

The Indian experience over the last decade or so and the work now in progress in different countries in the field of standardization of steel and steel products at national as well as regional levels clearly underlines the need for unification of standards and their alignment as much as possible with International Recommendations. To the extent that individual nations and regional organizations would be able to achieve this unification, they will draw the international trade and industrial community closer together. The developing nations of the world who have to depend on the proper utilization of their own resources have a special interest in this work in as much as commonly accepted standards will help them exchange their goods with the more developed countries of the world and thereby assist in the creation of better living standards for their own people.
