A. PRESENT STATUS, POTENTIAL PROSPECTS AND PLANS OF SMALL SCALE HYDROPOWER PLANTS.

Electricity supply for inhabited and economic centres located in remote rural areas with very low energy demand, such as most of the small towns, small mining districts, etc., in the Andes of Perú, represents a technical and socio-economic problem of a non-conventional solution, because the alternative of connecting them to the large transmission lines is too expensive. The possibility of using generating sets driven by internal combustion engines is not always advisable due to the necessity of relying on qualified personnel for the service, repairing and maintenance of the plants and due to the high costs of the fuel and its transportation to the station sites.

The peruvian Andes are very rich in hydraulic resources of small power which has still not been completely exploited. Considering that the economic and social integration of a great part of the peruvian population can not be postponed, it is necessary to support the use and development of small hydropower plants. It is also advisable, if possible, to standardize the plants equipment and components for the ease adaptation to the many possibilities of head and water flow rates combinations without suffering basic modifications of its components.

The use of small hydropower plants will also accelerate the social and economic development of the remote regions if the manufacturing of the most parts and components of the stations in regional workshops is encouraged. Appropriate design of the components will permit the standardized production with the result of a lower plant costs.

Figure 1, shows the distribution of the population of the small towns of Peru according to the National Census of Population of 1972. It can be made known that only 536 towns of the total have electric energy and that 410 of them are supplied by small power plants. From the 410 towns, 146 of them are supplied by small hydropower plants and 264 by thermal power plants. In general terms, it can be said that about 50 % of the total number of towns with a population between 1000 and 10000 inhabitants do not have electrical energy, but on the other side they have many possibilities of hydropower. Figure 2, shows the geographical situation of small towns in Peru.

To face up this situation, the government has recently announced the National Plan of Small Hydroelectric Plants, which has been outlined by the Ministry of Energy and Mining. The plan covers major goals related to the energy supplying for remote centres using the great amount of small power sites of the Peruvian Andes, the gradual replacement of the small thermoelectric plants by hydropower and the development of a local technology apt to design, manufacture, install, operate and maintain the equipment of the plants.

The plan anticipates the implementation of 50 projects of small plants for the period 1980-1985 with an investment of US \$ 12.5 millions.

Figure 3, shows briefly the distribution and technical data of 39 of the 50 projected stations. It can be noted, that 30 stations cover the lower range between 50 kW and 500 kW, 6 stations the range between 500 kW and 600 kW and only 3 the upper range between 800 kW and 1000 kW. The mini hydropower plants between 50 kW and 500 kW are therefore predominant.

Figure 4, gives information of the installed capacity of the electric power plants in 1975.

B. ORGANIZATIONAL SET UP INCLUDING DIVISION OF RESPONSIBILITIES AND TASKS FOR PLANNING, CONSTRUCTION, MANAGEMENT AND OPERATION OF SMALL HYDROPOWER PLANTS.

The activity of the electric energy in Perú depends on the Ministry of Energy and Mining, which by means of the General Board of Electricity, performs the functions of dictating norms and to manage, coordinate, promote and control the electricity activity.

The necessity of developing the small hydropower generation has become apparent. In november 1978, the Ministry declared of first priority the Programme of Small Hydroelectric Plants to be managed by a special Council. Later on, in december 1978, the Council recommends to the electricity state company ELECTRO PERU the creation of a special fund for financing the programme. The fund was approved and ELECTRO PERU will allocate the 15 % of its yearly income for financing the plan.

In december 1978, ELECTRO PERU has also created the Office of the Programme for Applied Technology (OPTA) which has the responsibility of supervising and coordinating the Programme of Small Hydroelectric Plants. For the implementation of the plan, ELECTRO PERU has also created 5 Regional Units of Exploitation. Figure 5, shows the division of responsibilities described before.

In a similar way, the Ministry of Industry and Tourism, by means of the Institute of Industrial Technology Investigation and of Technical Normalization (ITINTEC) is carrying out, from october 1978, an investigation programme on mini-hydropower plants in the range between 5 kW and 50 kW. The programme has as main goals to propose a method for the design, manufacturing, etc. of the plants as well as writing a practical handbook for designers and users.

It is also known that similar efforts in this field are being carried out by private companies like ELECTRO LIMA and HIDRANDINA and by universities like the National University of Engineering of Lima (UNI).

C. TECHNICAL, ECONOMIC AND ENGINEERING DATA OF RECENT SMALL HYDROPOWER PLANTS CONSTRUCTION INCLUDING INFORMATION ON WHO BUILT, WHO OWNS, WHO MANAGES, WHO FINANCES, ETC.

The information requested in this item will provide data about some small hydropower plants and about a new group recently put into service.

- Plant of Milloc (Lima): 1967, 12 kW, head of 40 m, flow rate of 40 lt/seg, 1170 rpm, altitud 4350 m, Michell-Banki turbine, ELECTROLIMA Co.
- Plant of Marcapomacocha (Lima): 1967, 120 kW, head of 12 m, flow rate of 250 lt/seg, 1200 rpm, Michell-Banki turbine, ELECTROLIMA Co.
- Plant of Churin (Lima): 45 kW, head of 28 m, 1200 rpm, altitud 2000 m, Francis turbine, ELECTRO PERU Co.
- Pilot Plant of Obrajillo (Lima-Canta): 1978-1980, 16 kW, head of 56.5 m, flow rate of 48 lt/seg, 1800 rpm, Michell-Banki turbine, PVC-pennstok, ITINTEC.

The following small hydropower plants has been put into service in 1979 by ELECTRO PERU Co.:

- Plant of Acos (Lima) of 150 kW.
- Plant of Tacabamba (Cajamarca) of 105 kW.
- Plant of Vischingo (Ayacucho) of 100 kW.
- Plant of Carnuarca (Ayacucho) of 24 kW.
- Plant of Huampalpa (Ayacucho) of 35 kW.

Figure 6, shows the geographical situation of existing small hydropower plants in Perú.

D. SALIENT TECHNO-ECONOMIC FEATURES IN SMALL HYDROPOWER PLANTS SYSTEMS APPLIED IN THE COUNTRY.

Perú has a surface of 1'285,000 Km<sup>2</sup> and is geographically divided into 3 natural regions (Figure 2), namely:

- the coastal region with a surface of 136000 Km<sup>2</sup> (11 %) which extends between the 0 m and 2000 m of altitude and has a variable wide between 50 Km and 100 Km.
- the mountains region (Andes region) with a surface of 385000 Km<sup>2</sup> (30 %) and extends from 2000 m altitude over the high Andes mountains towards the jungle.
- the jungle region with a surface of 764000 Km<sup>2</sup> (59 %).

From the hydrographic point of view Perú can be divided into 3 great basins, namely: the Pacific basin, the Amazon basin and the Titicaca Lake basin.

From the point of view of electric planning Perú can be divided in 4 zones, namely: the northern, central, southern and the eastern.

The Ministry of Energy and Mining with the cooperation of the West Germany government has recently finished the evaluation of the theoretical available hydroelectric potential of the country. This reaches the figure of 206108 MW, distributed in 29257 MW (14.2 %) for the Pacific basin, 176287 MW (85.5 %) for the Amazon basin and 564 MW (0.3 %) for the Titicaca Lake basin. Furthermore, the hydroelectric potential that can be technically developed is about 58346 MW with a production capacity of about 390775 million of kWh/year. This potential corresponds only to the developments greater than 30 MW. At present, scarcely between 3 % and 4 % of this potential has been exploited.

However, the previous estimation has not included the small scale hydropower developments which are mostly located in the sub-basins which have great heads (up to 300 m) and small flow rates (up to 500 l<sup>3</sup>/sec). Between

those limits it is expected to have about 1000 sub-basins apt to be transformed in about 1 million kW by employing small-scale hydropower plants. Most of the plants would operate with Pelton, Francis and Michell-Banki turbines.

The small hydropower plants in Perú may be classified according to the following ranges:

- Small hydropower plants: up to 500 kW
  - Mini-micro H.P. : up to 5 kW.
  - Micro H.P. : 5.5 kW to 50 kW.
  - Mini H.P. : 51 kW to 500 kW.
- Medium hydropower plants: 501 kW to 5000 (10000) kW.

With respect to the economic aspect, the cost of small scale and medium scale hydropower stations is relatively high. With reference to 1979, the costs are of the order of 2500 US \$/kW for the micro hydropower plants and range from 2000 US \$/kW for the mini H.P. to about 1800 US \$ for the medium H.P.

#### E. CAPACITIES AND CAPABILITIES FOR LOCAL MANUFACTURING OF EQUIPMENT IN THE FIELD OF SMALL HYDROPOWER GENERATION.

According to the degree of the technologic development of Perú, it can be stated that the country is capable to implement a plan for the manufacturing of small water turbines and related equipment. There are many private and some state factories and workshops with the experience for that purpose.

With respect to the penstock, local manufacturers produce piping of diameters up to 100 mm; greater sizes can be specially made by rolling and welding. ITIEMBO is also investigating lower cost piping alternatives by using materials other than steel like asbesto-cement,

polyethylene, polyvinyl-chloride (PVC), fiber glass, etc. These pipings are offered in the market in diameters up to 300 mm and can tolerate pressures between 10 kgf/cm<sup>2</sup> and 15 kgf/cm<sup>2</sup>. They are less expensive than steel, easier to transport and to install because of its easy adaptation to the ground profile, etc.

With reference to the manufacturing of water turbines, there are some workshops and factories with experience of more than 20 years in the construction of small Pelton turbines and in maintenance and repairing of large Pelton and Francis turbines, like HIDRANDINA Co. The Michell-Banki turbine is also an interesting alternative because of its lower cost and relatively easy manufacture. This turbine is, at present, being investigated mainly by ININTEC (Refs. 4-6) and also by the National University of Engineering (UNI) of Lima (Refs. 1-2-3) and HIDRANDINA Co. With respect to the Francis, this can be made by using the experience of the centrifugal pump manufacturers.

With respect to the manufacturing of electric generators, these are offered in units ranging between 3 kVA and 200 kVA but only for use in thermoelectric plants. ININTEC is also supporting an investigation programme for the adaptation of generators with 2 and 4 poles, for use in small hydropower plants by reinforcing the generator coils in such a manner that may stand runaway speeds of the order of twice the nominal speed of the turbine.

In a similar way exists great experience in the construction of dams, canals, buildings, etc. and the same with respect to the construction of transmission lines. Transmission towers of steel can be replaced by towers of wood by using the eucalyptus which grow abundantly in the peruvian Andes.

Figure 7, shows schematically a small hydropower plant.

F. EXISTING PROGRAMMES FOR DEVELOPMENT AND TRAINING  
IN FIELD OF SMALL HYDROPOWER.

The implementation of a massive programme of small hydropower development demands the participation of qualified personnel for the design, manufacturing, operation, managing and maintenance of power plants.

It is therefore necessary the planning of short, medium and long term courses in the universities, technical schools, etc., to train the engineers, technicians and skilled workers with hydropower knowledge.

Peruvian universities, by means of its Faculties of Mechanical, Electric, Civil Engineering should play an important role in this field by including in the curricula the necessary courses related to hydropower plants. In this respect U.N.I. has played and is playing this role by means of its Academic Departments of Energy and Mechanics, Electricity and Electronics, Hydraulic, etc. through investigation thesis, laboratory work, seminars, plant visits and academic courses. Most of the engineers who are at present engaged in the development of the hydropower generation are graduates from UNI.

With respect to the training of technicians, it is very important to emphasize the recently establishment of the Technical School of Hydraulic Technology (ETEMHI) of HIDRANDINA Co. The school has the specific purpose of providing courses for the training of qualified personnel for the operation and maintenance of small and large hydropower plants.
