INTRODUCTION

-1-

This report, prepared as a background paper for the First Consultation on the Building Materials Industry, is addressed to the situation of this industry in Brazil. Some complementary information is given about research in this field, in Brazil as well as in Latin America.

The difficulty of obtaining data which could be interpreted for the purpose of this work necessarily limited the number of materials to be surveyed, as well as the depth of the study.

These materials are: Portland cement, aluminum, plane glass, steel, glazed ceramic tiles and wood. Although not complete, the study of these materials shows some of the successes and problems which face the building materials industry in Brazil at this moment and so can help in the decision process for the future.

FOREWORD

-2-

This work is incomplete in scope and detailing mainly because the statistics necessary either were not available or were aggregated in a way in which it was not possible to extract the information pertaining the sector of interest, namely the building materials industry. This lack of acessible information is, by the way, one the main reasons why planning and planning implementation are so badly carried out, not only in Brazil but in the developing countries as a whole.

Main sources for this paper were Brazilian CNICC (National Commission for the Building Construction Industry) and IBGE (Brazilian Institute of Geography and Statistics). Much of the treated information was taken from a preliminary report on the construction industry in Brazil, prepared by Fundação João Pinheiro, to which the author wants to give his thanks.

REVIEW OF SOCIO-ECONOMIC DEVELOPMENT

The last two decades have seen the so called "Brazilian Miracle" and its end as well, in the sense that Brazil's enormous external debt has led the Government to take severe recessive measures. Inasmuch as the "miracle" reflected itself strongly in the building materials industry and the construction industries (large dams, roads, industrial plants, and an ambitious housing program) its end also reversed the high growth rate of these sectors, forcing many of the firms to reduce their size and, in some extreme cases, to close.

At the present moment what one can see is still a pessimistic vision: large civil works depended in the past of external funds and these funds are no longer available; on the other hand the national housing program, which depends essentially on internal savings and a special compulsory fund paid by employers on behalf of each employee is adversely affected by the economic recession.

The housing shortage is very large still and of course some funds will also have to be provided for high priority large works. However there is not, at this moment, a clear guideline to follow. Matters are not helped by the turmoil in the political scene but as soon as presidential elections have taken place undoubtedly the new development strategies will appear.

One can see, however, some tendencies: there will be more concern for quality and durability; users will have more to say in what refers to their interests, particularly in the housing field; decision decentralization will become more common. In short, one can expect with some certainty a more conservative approach to development.

CONTRIBUTION OF THE CONSTRUCTION INDUSTRY TO THE GROSS DOMESTIC PRODUCT AND THE GROSS FIXED CAPITAL FORMATION

· · ·

The available data show that the Construction Industry contributes with 4% to 5% of the Gross Domestic Product which oscillations have generally followed the variations of the country's economy and the industrial sector.

Attention must be paid to its high participation in the Gross Fixed Capital Formation, around 20%.

- PORTLAND CEMENT -

-13-

Basic raw materials for Portland Cement industry are lime and clay, both of which are found abundantly in Brazil. Portland cement can be made through two different manufacturing processes: dry process and wet process. The wet process, the first to be conceived, is much less used today, due to high needs of fuel oil. In Brazil, according to recent statistics, cement produced by in this way corresponds to less than 21% of the domestic output.

The dry process, widely used, has on the other hand, large advantages in fuel oil economies and so constitutes a out 75% of the total production.

Even so, compared to other industrial sectors, the cement industry is highy demanding of oil; in total production costs, 40% to 70% are due to energy costs, and in the total Brazilian oil needs, Portland cement industry is responsibile for using 12% (1982 data).

Generally speaking, cement industry is highly capital intensive, since labor participation in the global production costs is, in both processes, less than 3.5%. This sector is extremely important for the building industry, where more than 90% of its production is used. This characteristic strongly ties its development to the building industry rhythm and consequently to government's policies on large civil works, transportation and housing. It is worth stressing the fact that more than 2/3 of the total cement production is used in projects directly or indirectly related to the public sector.

In 1980 Brazil occupied the ninth place in the world as cement $prod\underline{u}$ cer. Erazilian cement output increased 161% in the 1971-1982 period, growing an average 9.1% yearly, much superior to the whole of the transformation industry in the same period.

More than half the companies in the sector were established in the last two decades and more than one third in the seventies.

In what refers to the sector being able to attend domestic needs the production has folowed, step by step, the evolution of demand, and, beginning in 1979, there was a small surplus quantity which was exported until 1981 when it ceased.

-14-

As to total production capacity, it is presently (1984) of about 35 million tons of clinker and 45 million tons of cement.

In 1982 the sector had 105 factories in operation, all of them belong ing to large private groups, Brazilian and foreign, government partic ipation being practically inexistent.

Three of these groups control more than half of the total installed capacity showing a very high degree of industrial as well as financial concentration.

ALUMINUM

Building industry is the largest demanding sector of the domestic aluminum market, and has used in the last two years about 23% of the total production. This participation will probably be kept, despite the decrease in the building industry's activities.

Aluminum is employed in building in a multitude of ways; window and door frames, partitions, roofing and structural elements. The material is mainly used as extruded profiles (about 70%), destined to frames; laminated aluminum, although with a smaller share, is being more and more used in roofing and ceiling systems.

Even so, compared to developed countries, the consumption of this material in Brazil can be considered low. While in Europe there is a utilization of about 20 kg per capita per year and in the United States this number reaches 30 kg, in Brazil we have 2,5 kg per capita per year.

Brazil presents extremely favorable conditions for the production of primary aluminum, due to the very high bauxite reserves and the abun dance of electrical energy, of extreme importance in aluminum production.

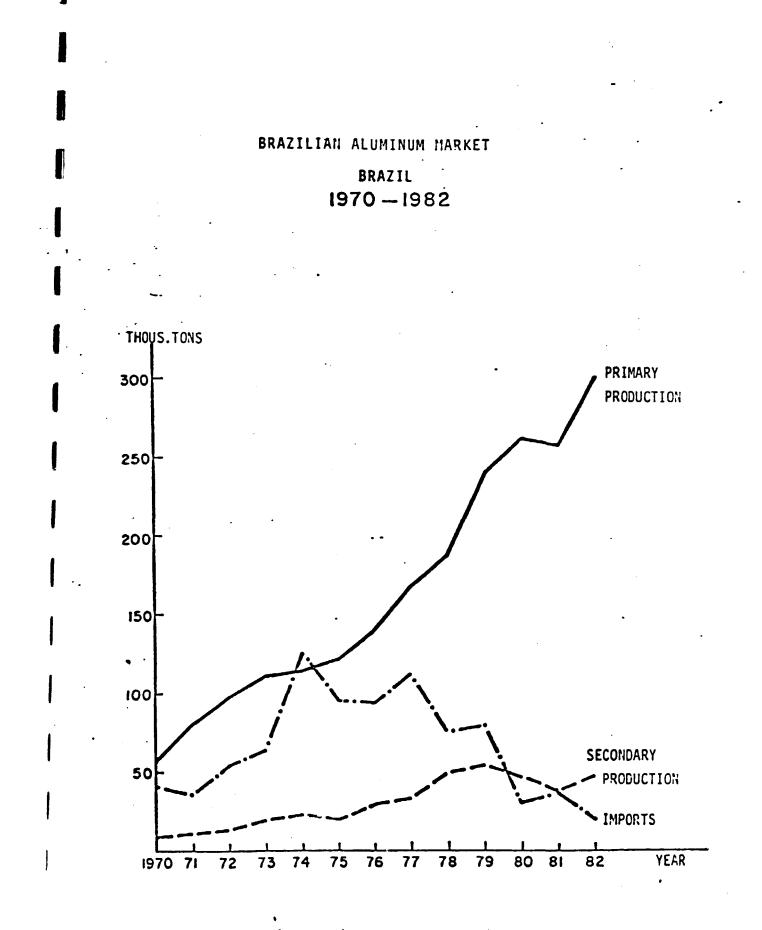

In market terms, the beginning of aluminum production dates from the fifties, when two companies, one of them foreign owned, started operation. Until the sixties, those two companies shared the market. In 1972 another foreign company established itself in Brazil and today the total production capacity is about 278 thousand tons per year. A new plant already in construction and the ampliation of one the already existing operations will raise this figure to 400 thousand tons per year in 1985.

- CERAMIC GLAZED TILES -

-23-

This material is widely used in houses, (kitchens, bathrooms, laundry areas) and also in swimming pools, restaurants, hospitals, always in locations which demand high standards of cleanliness, since it is extremely resistant to water and cleaning materials.

The tiles are the result of the industrial processing of a mix which main components are common clay, kaolin and feldspar.

They can come in a variety of colors and can also be printed.

The main characteristics of this industry in Brazil (mainly medium size and large companies) are its strong dependence on the building industry and the considerable concentration of supply and demand.

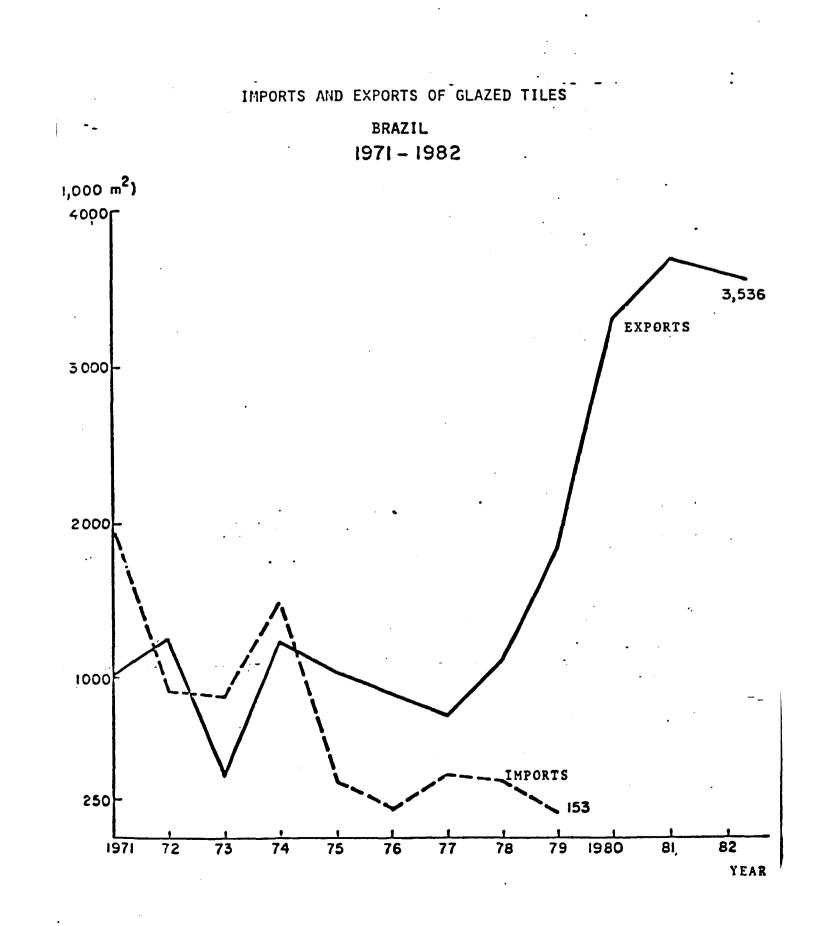

The eighteen Brazilian factories, belonging to twelve groups, have a total production capacity of about eighty and a half million square meters a year.

Supply is mainly concentrated in the South (47.8%) and Southeast (28.6%). One third of the total output is concentrated in the State of Santa Catarina.

On the demand side, more than two thirds lie in the states of São Pau lo and Rio de Janeiro. It is also worth mentioning that almost half of the total supply is in the hands of only three companies, indicating a high financial concentration in this sector.

Production figures show that the sector experienced until 1977 high growth indexes, having more than doubled its total output capacity as compared to the beginning of the decade. From 1977 on there was a 'steep decrease, and in 1982 total output figures fell down 13.5% as related to 1981. Due to the smaller demand, excess production capacity lies now around 35%. Imports of this material, already insignificant in 1975, were practically zero in 1979. Exports, on the other side, due both to the expan sion of the sector and the retraction of the domestic market show a rising tendency, representing, in 1982, about 6% of the total. The exported volume however, is not enough to compensate for the difficul ties faced in the internal market. Efforts to increase exports have not succeeded mainly because of economic recession affecting the main importing countries (Argentina, for instance) and competition of traditional exporting countries, such as Italy. There are also technical drawbacks (tiles' dimensions, for instance) and esthetical resistance to colors and print patterns in the U.S. and Canada, potential importing countries.

" PLANE GLASS -

Building industry is responsible for the demand of 60% of the total production of smooth glasses; the 40% left are destined to the automotive industry.

This demand concentration in only two sectors makes the glass industry extremely vulnerable to demand oscilations in those sectors. This situation is demonstrated by the sales decrease in the domestic market of about 20% in 1981, due mainly to the simultaneous activity decrease in the building and automotive companies.

Plane glass is made in Brazil by only four companies, all in São Paulo and with a total production capacity of 1540 tons/day. The three most important organizations are foreign owned.

In the production of plane glass more than thirty components are used, among which feldspar, aluminum, iron and soda ash. Part of the soda ash is still imported from East Europe but a new factory being built in the Northeast will be able to replace these imports.

BRAZIL - 1982

-28-

•

Brazil ranks 12th among world steel producers, due to the high growth indexes of the last decade. As a whole, Brazilian siderurgy grew, in the seventies, 180%, raising the production of raw steel from 4925 thousand tons in 1969 to 13891 thousand tons in 1979. More recently, however this sector is facing a sharp decrease in its growth, and in 1981 and 1982, negative figures, following, therefore Brazilian economical recession.

In general, Brazil is self-sufficient in laminated steel production, although in some periods it had to import high quantities of the material to meet domestic demand.

Due to the strong decrease in the internal market, this sector has been pursuing an agressive exporting policy, with the result that in 1982 the total of exports of laminated steel represented 19.3% of the total output. However even this good performance did not compensate for the fall in domestic demand and considering that the total production capacity of the sector is 20 milion tons/year, one can estimate excess production capacity as nearly 35%.

The building sector uses steel as one of its main intermediate materials and is surely the main consumer, with 28.4% of the total. This figure will probably remain the same until 1935 at least.

Even if the building industry is the main buyer of steel in Brazil, this participation is, in worldly terms, very low. In Japan, for instance, more than 50% of the total steel produced is destined to the building industry. This small share is explained by the fact that in Brazil reinforced concrete predominates in building technology as compared to steel construction.

Makers of laminated steel comprise 32 companies, with predominance of the private sector, either domestic or foreign.

-31-

Wood industry is intimately related to building industry, and more particularly with housing. This market uses mainly three kinds of wood: pine, comprising nearly half of the supply; "pinus" (refores ting wood) with about 20%; and other woods (Canela, Cambarā) with 30%.

Brazil has extensive areas covered by forests. A survey made in 1973 shows that almost all of the dense ones are in the North and Center-West, with respectively 82.5% and 9.3% of the total. However, although most of the resources are in those regions the wood industry is almost totally concentrated in the South and Southeast, near to the

main domestic markets. In 1979 both regions produced 98.4% of the total output of industrialized wood. Brazilian wood production reached its peak in 1973, following the economic boom. The number of saw mills grew from 14812 in 1970 to 17907 in 1975. In the year 1973 production of (wood in logs) reached 36.5 million m³ to fall, in 1979, to 31.5 million m³.

Exports of wood also reached their peak in 1973: 899 thousand tons in 1971, 1,124 thousand tons in 1973, falling drastically in the next two years. After this period though, exports showed a strong tendency to recovery and in 1980 the figures were 871,961 thousand tons.

The market structure: in 1980 15.053 firms shared the market, being 145 of large size, 994 medium and small size and 13.919 very small, representing therefore 92.45 of the total number of producers. This of course characterizes an extreme dispersion of this industry's productive structure.

The presence of either large companies and foreign owned firms is not significant: In 1979, 93.3% of the companies in the market were Brazilian and private-owned. It must also be stressed that this industrial sector has the lowest productivity and the smallest ave rage wayss in all industry.

-32-

RESEARCH ACTIVITIES

Main Institutions

There are in Brazil several important research institutions dealing with building materials, some of them very old, since this area is traditionally the first one to be approached.

. - 33-

Most of these organizations were created formerly as laboratories belonging to universities and afterwards became independent from tham as the demand for their services made it necessary a larger degree of autonomy, both administrative and technical.

All of them depend on large part for their existence on selling ser vices and obtaining research grants from private and governmental enterprises, with a small percentage of funds being allocated as subsidy for overhead, documentation, and for funding projects not immediately interesting to clients but which are recognized as important for the field.

Cooperation among the institutions has been until recently, not very intense, due, among several factors, to geographical separation, regional biases and competition for the same federal funds. Recently however the Brazilian Association of Industrial Research Institutions was created, aiming to minimize these differences and at the same time to help establishing a common technical competence. Brazil is also beginning to set up a Certification of Conformity system for industrial products and it is of course evident the necessity of a national network of laboratories to the success of this system.

On Going Programmes

The main line of research programmes has been, as a rule, looking for cheaper materials and building techniques, as well as the use of local materials and labor. This line however has several drawbacks in that industry in general does not take an interest in it, since from their point of view, very few of them allow for industrial economies of scale. This is the case for instance, of studies dealing with the use of rice husk ash and lime as a pozzolamic cement; soil cement in masonry applications as bricks, blocks and also as monolithic walls; plasters made with gypsum resulting from the production of phosporic acid. On a more industrial basis, several research projects dealing with replacement of asbestos in asbestos-cement products are under way, including technologies for manufacturing alkali resistant glass fibers.

In the same basis, reforestation woods, particularly "Pinus spp" are currently being used experimentally in the construction of low cost houses in the South of Brazil.

RESEARCH ACTIVITIES IN LATIN AMERICA

With the exception of Mexico, Brazil and Argentina, which have established important building and construction industries of their own, Latin American countries depend very much on imports of buil ding materials and technologies. This dependence leads also to a weak position in terms of research in the field, since innovation comes normally in the same way.

There are however some remarkable activities, mainly related to the use of indigenous materials and taking into account local conditions of climate and labor qualification.

Worth mentioning is the Andean Pact project PADT-REFORT, in Peru, which concerns the introduction of tropical wood as a building material; included in this project are personnel training lab equip ment, editing of publications in timber engeneering.

Undoubtedly one of the main problems which affect research in this field in Latin America is the almost complete lack of information about what each organization is doing.

The establishment of an <u>effective</u> information system for researchers in Latin America must therefore be considered as a primary goal in what regards policies for the advancement of in knowledge in the building materials' field.

Due regard to local conditions of climate, manpower and raw materials must be paid in every research project; it is widely known that many costly mistakes could be avoided, specially in low cost housing, if these factors had been respected.
