The Manufacturing-Service Sector Linkage:  
A Conceptual and Empirical Investigation

Introduction

The present study develops a general conceptual framework on the relationship between the manufacturing sector and the service sector. Part I of our cross-country study deals with aggregate relationships. In Section I-C of Part I, a decomposition technique is employed to analyze the source of growth of the service sector. Part II deals with disaggregate relationships. The concepts of Backward Dependency Ratio and Sectorial Sales Ratio are developed in Sections II-A to describe the linkages between the manufacturing sector and the service sector. In order to study the evolution of sectors over different stages of development, the regression technique developed by Chenery (1979) et al (see sections I-C, II-A and various sections in Part II) is employed. The present general framework can easily be applied to study other sectors and their relationships with the manufacturing sector.

Part I. Some Aggregate Relationships

I-A The Theoretical Framework

In the past, some work has been written on the growth of the service sector and its relationships with manufacturing and agricultural sectors. For example, Clark (1957) and Fisher (1939) had long predicted that countries could be expected to follow a sequence of primary, secondary and tertiary production in the course of development. The primary sector produces basic goods. The growth potential of this sector is somewhat limited. The secondary sector (manufacturing) produces goods for intermediate needs. The tertiary (service) sector produces luxury goods and intermediate inputs, in

form of various services, to other sectors. The potential of development of service industries in modern society is therefore, very good from these predictions.

There are three explanations for this phenomenon in the literature. The first one is the "Engel's Law" type of explanation based on the (income elastic) demand for services. As the economy develops, higher income per capita induces proportionally a much higher demand for services. The second explanation is based on the "productivity difference" between the service sector and other industrial sectors. The lower rate of increase in labour productivity in the service sector relative to manufacturing induces a rise in the price of services relative to other goods. This would further induce a continuous transfer of labour to the service sector. This productivity explanation also has its short comings. The increase in the relative price of services would reduce the demand for services through the price elasticity of demand. This would further reduce the expansion of the service sector.

The third explanation is the provision of services as intermediate inputs to the manufacturing sector. This development reflects the division of labour across industries as the economy grows. The growth of services is related to the increasing demand from the manufacturing sector for intermediate service inputs. This explanation also has its short comings. This means, the decline of the manufacturing sector at the Advanced Stage of industrial development would reduce the expansion of the service sector. In the Early Stage of economic development, the informal sector which is unique to less developed countries begins to grow. This growth is a result of the rapid rural-urban migration. The informal sector basically absorbs the new urban migrants and provides small-scale services mainly catering to the needs of low-income groups. Hence, the employment in the service sector is larger than the employment in the manufacturing sector.

At the Intermediate Stage of economic development, a network of interindustry linkages begins to develop. Output in the manufacturing sector rises rapidly. The employment in the service sector also rises partly through the increase in interindustry demand for services and partly through the increase in (final) consumption demand for services. Employment in the

service sector probably rises at a slower rate than those in the manufacturing sector.

At the Advanced Stage of economic development, the manufacturing sector begins to decline in absolute terms. This decline is consistent with the "product cycles" theory, that the traditional "smokestack industries" begin to move to newly industrialized countries with lower labour costs. The employment share of social services tends to rise due to the (elastic) income induced demand for social services (the Engel's Law) and the "technological gap" between the manufacturing sector and service sector. There are, however, factors that work against the expansion of employment in the service sector. The first one is, the decline in the manufacturing sector may lead to a decline in the service sector through the manufacturing-service linkage. The second one is, the rise in the price of services from the "technological gap" may lead to a decrease in the demand for services through the price elasticity of demand. The net employment effect on service sector is in fact, unclear.

At the Advanced Stage (or the deindustrialization stage) of development, the rate of employment growth of the manufacturing sector begins to fall while the rate of employment growth of the service sector begins to rise. There must be a turning point where the employment growth rate of the two sectors are identical. Beyond this point, the employment growth rate of the service sector begins to rise faster than the manufacturing sector. The main source of employment growth of the service sector must come from the manufacturing sector.

#### I-B Empirical Framework

In our empirical analysis, twenty-six countries are selected. The sample is selected to give a roughly equal number of countries in each of the following categories; the industrial market economies, the upper middle-income economies, the lower middle-income economies and the low-income economies. The selection is limited by availability of data from the International Labor Organization (ILO) statistical yearbook. Less developed countries with a

small population (less than two million) are excluded. The oil exporting nations that have very small agricultural sector are also excluded.

Employment data used in our study is compiled from the ILO, Yearbook of Labour Statistics and from the Handbook of World Development Statistic (UN 1983). The ILO started to collect employment data on the service sector as early as 1960 (for some countries 1963). The present study utilizes all the available data from 1960 to 1983. The average values of all these years were taken for our analysis. The period 1960 to 1983 is subdivided into two: the pre-oil shock period and the post-oil shock period. The data between 1972 to 1975 is ignored since it reflects structural changes from the oil shock.

The first part of the study is a cross-country decomposition analysis. The source of employment growth of the service sector is decomposed into three components; that which come from the agricultural sector, that which comes from the manufacturing sector and that which come from other industrial sectors. The second part of the study is regression analysis. This analysis follows the traditional analysis developed by Chenery (1979), Chenery and Taylor (1968), Chenery and Syrquin (1975) and recently by Gemmell (1983). These works basically argued that the employment growth of sectors varies ultimately with the "level of development". The latter can be approximately by the per capita income and population size. A cross-country comparison is used because different countries are at different levels of development.

Finally, the above techniques are used to examine the product (GDP) growth rate of the service sector, the manufacturing sector and the agricultural sector. The results generally confirm the conclusions in the employment studies.

### I-C Decomposition Analysis

The growth rate of employment of the service sector  $r^s$  can be decomposed into the following components:

$$r^s - r = A^a(r^s - r^a) + A^m(r^s - r^m) + A^o(r^s - r^o) + A^e(r^s - r^e) \quad (1)$$

$$r = A^a r^a + A^m r^m + A^o r^o + A^s r^s + A^e r^e \quad (2)$$

$$A^a + A^m + A^o + A^s + A^e = 1 \quad (3)$$

where  $r$  is the total employment growth rate in the economy.  $r^a$ ,  $r^m$ ,  $r^o$ ,  $r^s$  and  $r^e$  are the employment growth rate in the agricultural sector, manufacturing sector, other industrial sectors (mining, construction and electricity and gas) and residual sectors (error and omissions etc.) respectively.  $A^a$ ,  $A^m$ ,  $A^o$ ,  $A^s$  and  $A^e$  are the employment share of agricultural sector, manufacturing sector, other industrial sectors and residual sectors respectively. They must sum up to 1 as stated in equation (3). The left hand side of equation (1) is the growth of the service sector employment beyond the total employment growth rate of the economy. This can be decomposed into four components as in the right hand side of equation (1). The first term  $A^a(r^s - r^a)$  is the contribution of labourers from the agricultural sector to the service sector. The second term is the contribution of labourers from the manufacturing sector, the third term is the contribution from the other industrial sectors, and the fourth term is the contribution from the residual sector (or simply, error and omissions). This decomposition is definitional, not causal. This crude decomposition does tell us from which sector the labourers are coming when the service sector expands.

Table I-1 presents the decomposition results. The percentage contribution of each sector are presented ( $= A_i(r^s - r^i) / (I r^s - r I) \times 100\%$ ). The value in the denominator  $I r^s - r I$  is in absolute value. Hence, each numerical value in Table I-1 would carry a sign identical to the sign of  $r^s - r^i$ . The post- and pre-oil shock periods are distinguished.

Source: Data compiled from ILO, Yearbook of Labor Statistics and Handbook of World Development Statistics, UN 1983.

The following observations are in order.

(1) From the early period (1960-1970) to the later period (1975-1983), the source of employment growth of the service industry that comes from the agricultural (manufacturing) sector goes down (up). This pattern is more pronounced in the industrial market economies and less pronounced in the lower middle-income economies. This pattern confirms that the employment share of the agricultural (manufacturing) sector is decreasing (increasing) with time and with the level of industrialization. It also confirms that the declining (increasing) growth rate in the agricultural (manufacturing) sector is gradually petering out (see equation 1).

(2) It can be observed that the service sector is the leading sector in employment growth (signs in the three columns are positive) among the high-income countries and that the manufacturing sector (or other industrial sectors) is the leading sector in employment growth (sign in the second (or third) column is negative) among the lower-income countries. The same decomposition is carried out using GDP growth rates. In Table I-2,  $g$ ,  $g^a$ ,  $g^n$ ,  $g^o$ , and  $g^s$  is the GDP growth rate of the entire economy, the agricultural sector, manufacturing sector, other industrial sector and the service sector.  $B_a$ ,  $B_m$ ,  $B_o$  and  $B_s$  are the GDP sectorial share of the respective sectors.

Table I-2 presents the GDP growth rate decompositions. Two observations are in order.

(1) In the earlier period (1960 to 1971), the second column in Table I-2 is negative. In the later period (1976 to 1980), most of the negative signs in the second column turn positive. This means, the GDP growth rate of the manufacturing sector is faster than the GDP growth rate of the service sector in earlier periods; in later periods, the service sector in most of the sampled nations grows faster than the manufacturing sector.

(2) In the first column of Table I-2, most of the sample countries (except 5) have a larger numerical value in the earlier period than in the later period. These two observations more or less confirm the results in the employment

decomposition analysis. The decomposition study on GDP is not as clear as the decomposition study on employment. In the work by Chenery and Syrquin (1975), they also obtained clearer results in their employment study than in GDP study.

#### I-D Regression Analysis

This section examines the relationships of the agricultural sector, the manufacturing sector, other industrial sectors and service sector at different levels of development. Following Chenery (1960), Chenery and Taylor (1968) and others, we use income per capita across country to approximate the level of development. The size of population is also used as a proxy for the size of domestic market. The employment share of these four sectors are examined in Table I-3 and Figures I-1, I-2, I-3 and I-4. The differential employment growth rates of these sectors (i.e.  $r^s - r$ ,  $r^m - r$ ,  $r^o - r$ ,  $r^a - r$ ,  $r^m - r^a$ ,  $r^m - r^s$ ,  $r^s - r^a$ ) are shown in Table I-2, and Figures I-5 to I-11.

In the regression equations, dummy variables are used. D1 and D2 are the dummies for periods (1960-1972) and (1975-1983) respectively. D5, D6, D7 and D8 are dummies for the structure of sample countries. According to Chenery and Syrquin (1975) and the updated study by UNIDO (1980), countries can be grouped according to their policy orientations. They are:

- (1) the primary specialization countries ( $D5=1$ ,  $D6=D7=D8=0$ );
- (2) import substitution countries ( $D6=1$ ,  $D5=D7=D8=0$ );
- (3) balanced development countries ( $D7=1$ ,  $D5=D6=D8=0$ ); and
- (4) industrial specializing countries ( $D8=1$ ,  $D5=D6=D7=0$ ) (see Appendix B).

In our regression analysis, many functional forms have been tested. Only the best functional forms are reported. The double log functional form is not used because  $r_i$  and  $r$  sometimes take negative values.

In the diagrams, the stars (\*) are the simulated values from the modified regression equations, which consists of all the right hand side variables (of  $Y$  and  $N$ ) except the dummy variables. For example, take the first equation in Table I-3. Let  $z$  be  $z = 1.636 - 0.263\ln(Y) + 0.022(\ln(Y))^2 - 0.272\ln(N) + 0.031(\ln(N))^2$ . The (\*) in the figures is the simulated value of  $z$  with

respect to Y. The value of N is the average N of the sample countries. The alphabets are the "adjusted" data points (observed values). Because of the way z (or the stars in the Figures) is defined, the observed values of A<sup>s</sup> must be adjusted by the dummy variables. The adjusted values are simply  $= A^s - 0.053D2 + 0.022D5 - 0.148D6 - 0.06D8$ . These adjusted values are plotted on the Y-axis. The advantage of this method is it is not necessary to plot one equation for each dummy variable. Noted that some of the t-values (in brackets) are low for variables y and the dummies. This is due to multicollinearity among these variables. The F-test without the y and higher orders of y variables (not reported here) shows that the impact of the variables y and higher orders of y is statistically significant. The F-test without all the dummies (i.e. all of D5, D6, D8) shows that the dummy variables are statistically significant explanatory variables. From these regressions and simulations, the following features are found:

- (1) The employment share of the manufacturing sector rises with the level of development and peaks at a level between \$ 4,500 - \$ 6,000 per capita (1970 constant US dollar). Then the employment share of the manufacturing sector starts to fall (see Figure I-3). The product (GDP) share of the manufacturing sector also shows the same pattern (Figure I-13).
- (2) The decline of the manufacturing employment seems to peter out when per capita income has reached a high level. In Figure I-8, the curve of  $r^m - r + 0.17D5 - 0.1D5 + 0.04D6 - 0.13D8$  bends upwards towards zero at around \$ 8,000 per capita. However, the slowing down of the product growth rate of the manufacturing sector does not seem to peter out. When per capita income has reached a high level; in Figure I-19, the curve of  $g^m - g + 0.15D2 - 0.05D5 + 0.05D6 - 0.13D8$  does not seem to bend upwards towards zero at high per capita income.
- (3) The employment share in the service sector falls rapidly and then rises again slowly at low level of per capita income (see Figure I-1). This confirms the pattern of development in the Early Stage where the employment in the informal sector dominates the employment in the manufacturing sector. The employment share of services goes down as the employment in the manufacturing sector begins to grow. The employment share of services then rises slowly again as the economy moves well into the Intermediate Stage of development.

(4) In Figure I-1, when per capita income is very high, service sector employment, in fact, rises at a slower rate. In Figure I-11,  $r^s - r + 0.01D2 + 0.02D5 + 0.04D6 - 0.12D8$  also falls with the level of development.

(5) The product share (GDP) of services in Figure I-15 also shows that when per capita income is very high the product share of services tends to rise at a slower rate. Figure I-22 suggests that the product growth rate of services,  $g^s$ , tends to be the same as the GDP growth rate of the economy when per capita income rises.

(6) Noted that in Figure I-11, when per capita income is around \$ 8,000,  $r^s - r + 0.01D2 + 0.02D5 + 0.04D6 - 0.12D8$  is around -0.05. The data points G, I, and K suggest that  $D2=1$ ,  $D8=1$ ,  $D5=D6=0$  (see Figure I-1, footnotes). Hence,  $r^s - r$  must take a positive value of +0.11. That is the service sector employment growth rate is larger than the average employment growth rate.

(7) The actual and estimated differential growth rate between  $r^m$  and  $r^s$  are presented in Figure I-6. At higher per capita income, the difference between  $r^m$  and  $r^s$  gets smaller. A careful examination of  $r^m - r$  and  $r^s - r$  reveals that the value in  $r^m - r$  is much larger than  $r^s - r$ . Thus,  $r^m - r^s$  reflects mostly the dominating behavior of  $r^m - r$ .

(8) In Figure I-6, when the per capita income is around \$ 2,700,  $r^m$  approximately equals  $r^s$ .\* The manufacturing sector employment is slowing down to the same rate as the service sector which is rapidly rising. The Intermediate Stage of development must have finished and the Advanced Stage of economic development must have begun. T' : GDP growth rate regression in Figure I-17 suggests this turning point occurs at a higher per capita income:  $g^m$  equals  $g^s$  at around \$ 3,500.\*\*

---

\* country "j" (Italy 1960-1972) has a per capita income of around \$ 2,700. This means,  $D2=0$   $D5=D6=0$ ,  $D8=1$ .  $r^m - r^s = -0.02 - 0.169D2 + 0.125D5 - 0.006D6 + 0.025D8$  approx. 0. (see equation 4 Table I-2).

\*\* country "l" (France 1960-1972) has a per capita income of around \$ 3,500. This means  $D2=D5=D6=0$ ,  $D8=1$ . Hence,  $g^m - g^s = -0.125 - 0.166D2 + 0.045D5 - 0.043D6 + 0.147D8 = 0.022$  approx. 0.

(9) The agricultural sector is declining with the level of development either in terms of employment share or in terms of product share (see Figures I-2 and I-12). The differential growth rates of  $r^m - r^a$ ,  $r^s - r^a$ ,  $r^a - r$ ,  $g^m - g^a$ ,  $g^s - g^a$  and  $g^a - g$ , (in Figures I-5, I-7, I-9, I-16, I-17, I-20) also confirm this trend.

(10) The other industrial sectors (mining, construction and electricity and gas) expand rapidly in the Early Stage of development. Then at the Intermediate Stage and the Advanced Stage, these sectors begin to decline. This pattern is clearly shown in Figures I-4 and I-14. The differential growth rate pattern of  $r^o - r$  and  $g^o - g$  also confirm this (Figure I-10 and I-21). One plausible explanation is: in the embryonic stage of development, the other industrial sectors are important for the infrastructure of the economy. In subsequent stages of development the importance of this role gradually diminishes.

#### I-E Discussions

From points (4) and (5), the service sector does not seem to "take-off" into self-sustained growth in the Advanced Stage of development. This sector is growing, but at a slower rate. Although the employment growth rate of the service sector is higher than the national employment growth rate average, this difference in growth rates declines gradually when the economy reaches the Advanced Stage of development. One plausible explanation is the offsetting factors discussed earlier. When the manufacturing sector declines in the Advanced Stage, the service sector must be affected through the manufacturing-service linkage. In addition, the "productivity gap" can result in a higher service price which can force the service sector to decline through the price elasticity of demand.

Finally, the behavior patterns of the manufacturing sector, agricultural sector and other industrial sectors seem to conform with the pattern of development described earlier.

## Part II. Some Disaggregate Relationships

The second part of the present study deals with the linkages between the manufacturing sector and the service sector. The input-output tables of twenty-six countries are employed for this study. The service sector is also broken down into three distinct categories: distributive service, producer services, personal services and social services. Each of these categories will be discussed separately in sections II-C, II-D, II-E and II-F. The differences in Forward, Backward and Total linkages between these sectors will be compared in section II-H. The average propensity to consume of these sectors will be presented in section II-I.

### II-A The Conceptual Framework

Two concepts are employed to describe the symbiotic interrelationship between sectors.

The Backward Dependency Ratio and the Sectorial Sales Ratio. The Backward Dependency Ratio of the jth sector on input i,  $iB_j$ , is defined as:

$$iB_j = a_{ij} / \sum_j a_{ij}$$

where  $a_{ij}$  is the value of the input-output coefficients (imports included). This ratio indicates how important or critical input i is to sector j. The Sectorial Sales Ratio of sector i with output going to the jth sector,  $iF_j$ , is defined as:

$$iF_j = a_{ij} / (\sum_i a_{ij} + C_i)$$

where  $a_{ij}$  is the value of the input-output coefficient (excluding imports) and  $C_i$  is the domestic consumption and export demands of sector i. The output of sector i goes to intermediate (input) demands and final consumption demands.

This ratio indicates how important the sales to sector j is from the viewpoint of sector i.\*

An innovative feature of the present empirical study is to disaggregate the service industry into four distinct categories. The service sector represents a rather heterogeneous mixture of diverse activities. We employ the classification system suggested by Gershuny and Miles (1983) and categorize service activities into two major groups. Marketed services and non-marketed services. These two major groups are further subdivided into finer and more homogeneous groups as follows:

(A) Marketed Services

(1) Distributive Services

- a. transportation and storage
- b. communication
- c. wholesale and retail trade (excluding eating and drinking places)

(2) Producer Services

- a. banking, credits, and other financial services
- b. insurance
- c. real estate
- d. engineering, architectural services
- e. accounting and bookkeeping
- f. business services
- g. legal services

(3) Personal Services

- a. domestic services
- b. hotels and lodging places
- c. eating and drinking places
- d. repair services
- e. laundry and dry cleaning
- f. barber and beauty shops
- g. entertainment and recreational services

(B) Non-Market Services

(4) Social Services

- a. medical, health, hospitals
- b. education
- c. welfare
- d. non-profit organizations
- e. public administration, postal, legal, mi... services
- f. professional and social services.

---

\* when both ratios  $iBj$  are large, sector j "depends" heavily on sector i as the source of input and the destination of output.

. The present study also subdivides the manufacturing sector into three categories at the (ISIC) two-digits level. This classification is based partly on the degree of industrial processing accumulated in a particular commodity. The categories are:

- (1) Agrofood processing and light industries (AL):  
ISIC 31, 32 and 33;
- (2) Energy and basic industries (EB):  
ISIC 34, 35, 36 and 37;
- (3) Capital goods industries (CG):  
ISIC 38;

Since the above classification is a bit arbitrary, a t-test is used in our empirical work to ensure the means and variances of each classified category are distinct from each other.

Finally, the Backward Dependency Ratio and the Sectorial Sales Ratio between the manufacturing sector and the four categories of service subsectors are examined for twenty-six countries. Inferences on the symbiotic relationships between manufacturing and services over different stages of development can be drawn from cross-country comparisons of these two ratios. This study is repeated for the case where the manufacturing sector is subdivided into three categories. This level of disaggregation also reveals some details of the interrelationships between the manufacturing subsectors and services. Another more detailed disaggregation of the manufacturing sector into eight categories (ISIC 31 to 38) is preformed. This more refine analysis is used to confirm and cross-check the results of previous cases.

Under these categories, the Backward Dependency Ratio and the Sectorial Sales Ratio of various sectors, classified by country's per capita income, are presented in Tables II-II to II-78. Each table is supplemented by a t-test for each income group. Regression analysis on every Backward Dependency Ratio and every Sectorial Sales Ratio are also preformed. The explanatory variables are the level of per capita income, populaton size, a dummy variable D2 to distinguish whether the input-output table is compiled before (D2=0) or after the "oil shock" (D2=1), and three more dummy variables (D5, D6, D8) to distinguish countries according to their structure (see Appendix B). Only the "best fit" functional forms are presented in Tables II-5 to II-10.

II-B Description of Data

The input-output tables of twenty six countries (UNIDO data base) are chosen for our study. This sample is selected in such a way to give a balanced number of low income countries, lower middle-income countries, upper middle-income countries and industrial market-economy countries. Less developed countries which have a small population (less than one million) are excluded. Countries with incomplete recording of the service sector in the input-output tables are also excluded.

The following sources of statistical errors are present in our study.

(1) The input-output tables are compiled in different years between 1968 and 1975. During these turbulent years the world economies had undergone some serious structural changes (e.g. the "oil shock").

(2) In the input-output tables of most less developed countries, import values are included in the coefficients. There are no separate tables to record imports. The calculations of forward linkage and Sectorial Sales Ratio are, therefore, bias. It is possible for the value of the forward linkage and Sectorial Sales Ratio (e.g. see Appendix D, Kenya and Indonesia) to be greater than one.

(3) There are also errors in our estimations due to different classification method employed by different countries. Some major regrouping work is necessary to standardize all the input-output tables.

(4) The recording of the input-output values for social services are grossly bias. Since most of the social services appear as public goods, it is difficult to record the exact contributions from this particular sector. Very often the input-output coefficients with respect to social services record zero values in places where they obviously should not.\*

---

\* Because of this reason (and also point (3) above which also give a zero entry), we abandoned the double log form of equations in our regression. For those entries that do not have zero values, the double log forms generally give better results (not reported here).

Table II-1(a) Backward Dependency Ratio at Different Level of Aggregation

SS	X	(+, +) <sup>w</sup>	(+, +) <sup>w</sup>	X	X	X	X					

Notes:

- Agrofood processing and light industries: ISIC 31, 32, 33;
- Energy and Basic product ISIC 34, 35, 36, 37;
- Capital Good Industries ISIC 38;
- X indicates no significant statistical relationship between the respective ratio on (Y,N);
- (+, -) the sign in brackets (+, - or -), indicates the sign of the regression coefficient that is significantly (5%) positive, negative or insignificantly different from zero. The first (second) sign in bracket is equivalent to the sign of partial derivative with respect to the Y(N) component;
- "w" superscript distinguishes that the statistical relationship, as indicated by a lower value of R<sup>2</sup>, F-statistic or t-statistic, is weak.

Table II-2(a) Sectorial Sales Ratio at Different Level of Aggregation

Notes:

See Table II.1.2

II-C Distributive Services (DS)

Tables II-11, II-5, II-1 and II-2 summarize the role of DS. Among other things, these tables highlight the following:

- (1) DS plays a central role in the intersectoral dependency between manufacturing and services. In first place, the value of input purchase (Backward Dependency Ratio) and the value of output sales (Sectorial Sales Ratio) of DS depends heavily on the manufacturing sector (particularly, Energy and Basic Products (EB)) in comparison with other service sectors. The Backward Dependency Ratio of DS on the manufacturing sector range between 0.3 to 0.4, the largest in comparison to other services. The Sectorial Sales Ratio (range between 0.1 to 0.18) is also the largest in comparison to other service sectors. In the second place, the input purchase and the output sales of the manufacturing sector towards DS, are the largest among all the service sectors.
- (2) The Backward Dependency Ratio and the Sectorial Sales Ratio (at a more disaggregated level) of DS towards the manufacturing sector decrease as the level of income per capita rises (Tables II-1 and II-5). The Backward Dependency Ratio and the Sectorial Sales Ratio of DS towards other services rise as the level of income per capita rises. This seems to suggest two things. A) As the economy becomes more developed, services in general, become more specialized and more skill-intensive. The inputs of DS gradually requires more and more sophisticated and skill-intensive services at more advanced stages of development. And, B) the manufacturing products become a less critical input to DS as the economy develops.
- (3) DS seems to rely on itself rather substantially as a source of input. The Backward Dependency Ratio of DS on DS is approximately 0.31.

Table II-3 DISTRIBUTIVE SERVICE

(I) Backward Dependency Ratio

(A) Manufacturing Sectors

$$MBDS = 0.44 - 4.28 \times 10^{-9} \times Y^2 + 1.94 \times 10^{-4} \times N - 0.15D5 - 0.006D6 - 0.078D8$$

- A means accept the null hypothesis that the means are equal.

II-D Producer Services (RS)

Since producer services consist of financial services and other professional (technical) services, this sector serves the entire economy rather than concentrating its services to a few specific sectors. Tables II-1, II-2, II-6 and II-21 reveal the following:

- (1) The Backward Dependency Ratio of other service sectors on manufacturing products range between 0.33 to 0.45. This ratio is much lower for producer services. The average value is about 0.18. The Sectorial Sales Ratio of producer services to manufacturing is about 0.12. Hence, in terms of input and output of producer services towards manufacturing, producer services seem rather independent of the manufacturing sector.
- (2) The manufacturing sector becomes more and more dependent on producer services as the economy develops to the Advanced Stage. This can be illustrated by the Backward Dependency Ratio and the Sectorial Sales Ratio of the manufacturing sectors towards producer services (Tables II-1, II-2).
- (3) Distributive services also become more and more dependent on producer services as the economy develops to the Advanced Stage. The Backward Dependency Ratio and the Sectorial Sales Ratio of distributive services towards producer services can illustrate this (Tables II-1, II-2 and II-6).
- (4) The sales of producer services to distributive and social services decrease as per capita income rises (see the Sectorial Sales Ratio in Table II-2).
- (5) Producer services seems to rely on themselves rather heavily as a source of input. The Backward Dependency Ratio of producer services on producer services is approximately 0.37.

Table II-10 PRODUCER SERVICES

(I) Backward Dependency Ratio

(A) Manufacturing Sectors

$$ALBRS = 0.031 - 1.67 \times 10^{-5} \times Y - 0.013D5 - 0.009D6 + 0.098D8 \quad F = 2.16; * \quad R^2 = 0.29$$

(1.17)      (2.47)      (0.40)      (0.27)      (2.25)

$$31BRS = 0.014 - 1.64 \times 10^{-5} \times Y - 0.006D5 + 0.002D6 + 0.099D8 \quad F = 2.48; \quad R^2 = 0.32$$

Note: IND: Industrial market economies;

UMI: Upper Middle-income economies;

LMI: Lower Middle-income economies;

LI: Low income economies;

- numbers in brackets are the t-values of the difference in mean;

- R means reject the null hypothesis that the means are equal;

- A means accept the null hypothesis that the means are equal.

II-E Personal Services (ES)

In the early stage of industrialization, personal services are the informal sector of the economy. At this stage, personal services are relatively labour-intensive and unsophisticated services, mainly catering to the rural poor and urban masses. At a later stage of industrialization, the range of personal services expands. The services provided become increasingly specialized and increasingly skill-intensive. The informal sector virtually disappears and is replaced by a more sophisticated personal service sector. Tables II-1, II-2, II-7 and II-31 to II-40 reveals the following.

(1) The Sectorial Sales Ratio of personal services to manufacturing is small (approx. 0.05). The Backward Dependency Ratio and the Sectorial Sales Ratio of manufacturing sector towards personal services are small (0.013 and 0.02 respectively). However, the Backward Dependency Ratio of personal services on manufacturing is rather big (approx. 0.44). These figures suggest that other than this significant amount of inputs of manufacturing product (mostly processed food, beverage and tobacco (Table II-35)), to personal services, the economic relationship between manufacturing sector and personal services in general are very weak.

(2) The Backward Dependency Ratio and the Sectorial Sales Ratio of the manufacturing sector towards personal services rise with the level of industrialization. The Sectorial Sales Ratio of personal services to manufacturing also rises with the level of development. This is perhaps due to the growing importance of repair services to the manufacturing sector in the process of industrialization in spite of the low volumes of inputs and sales of these sectors as discussed in the preceding paragraph. This also reflects the structural change that takes place in the personal services, i.e. from informal services to more sophisticated services.

(3) The Sectorial Sales Ratio of Distributive Services to personal services also rises with the level of development.

(4) Different from distributive services and producer services, personal services depends very little on itself as an input (ESBES approx. 0.086)

II-F Social Services (SS)

Social services go through some fundamental changes in the process of industrialization. In the early stage of industrialization social services are provided through non-market mechanism: for example, health and old age care are provided by the immediate family in the Early Stage. At the later stage of industrialization, social services are provided mostly by the government through the political process. This is due to the public good nature of some social services. Thus, the contributions of social services to industrialization and to the manufacturing sectors go beyond the intersectorial input-output relationships. The following conclusions can be drawn from Tables II-1, II-2, II-8 and II-41 to II-50.

- (1) The Backward Dependency Ratio of social services on manufacturing is around 0.34. This shows a significant input of social services is from the manufacturing sector (mainly, the Energy and Basic industries). The sales of social services to manufacturing (the Sectorial Sales Ratio) is very low. The sales and purchase of manufacturing sector to and from social services are also very low. (Sectorial Sales Ratio and Backward Dependency Ratio are around 0.01). As mentioned above, since most of social services have the nature of public goods, this weak relationship between manufacturing products and social services understates the actual relationship between these two sectors.
- (2) At a later stage of development, the energy and basic products become a less important input to social services (EBBSS falls as  $y$  rises). On the contrary, social services become a more important input to the capital good industries as the economy develops (both SSBCG and SSFCG rise as  $y$  increases).

Table II-24 SOCIAL SERVICE

(I) Backward Dependency Ratio

(A) Manufacturing Sectors

$$EBBSS = 0.184 - 3.51 \times 10^{-9} \times Y^2 + 0.98 \times 10^{-3}N - 0.13D5 - 0.02D6 + 0.02D8$$

(2.95)      (1.66)                (4.38)      (1.70)      (0.26)      (0.22)

$F = 4.31; R^2 = 0.52$

$$34BSS = 0.049 + 4.92 \times 10^{-7} \times N^2 - 0.015D5 - 0.017D6 - 0.002D8$$

(2.36)      (3.68)                (0.55)      (0.63)      (0.07)

$F = 3.67; R^2 = 0.41$

$$35ESS = 0.135 - 2.50 \times 10^{-9} \times Y^2 + 7.20 \times 10^{-4} \times N - 0.117D5 - 0.007D6 + 0.003D8$$

(2.72)      (1.48)                (4.06)      (1.92)      (0.11)      (0.04)

$F = 3.93; R^2 = 0.50$

8

(B) Service Sectors

$$RSBSS = 0.03 + 2.05 \times 10^{-9} \times Y^2 - 0.00015N + 0.032D5 + 0.019D6 + 0.124D8$$

(0.69)      (1.33)                (0.90)      (0.57)      (0.33)      (1.84)

$F = 3.98; R^2 = 0.50$

$$SSBSS = 0.024 + 2.92 \times 10^{-9} \times Y^2$$

(1.38)      (3.22)

$F = 10.39; R^2 = 0.30$

(II) Sectorial Sales Ratio

(A) Manufacturing Sector

$$SSFCG = - 0.014 + 0.0015\ln(Y) + 0.0011\ln(N) + 0.002D5 + 0.0005D6 + 0.004D8$$

(2.15)      (1.63)                (1.55)      (0.77)      (0.20)      (1.38)

$F = 3.85; R^2 = 0.49$

(B) Service Sectors

$$\text{SSFSS} = 0.004 + 1.35 \times 10^{-9} \times Y^2$$

(0.55)      (3.89)

$$F = 15.17; R^2 = 0.39$$

Forward Linkage (FL)

$$\text{FLSS} = 0.003 + 2.50 \times 10^{-9} \times Y^2 + 0.036D5 + 0.005D6 + 0.006D8$$

(0.11)      (2.45)      (0.98)      (0.14)      (0.12)

$$F = 2.95; R^2 = 0.36$$

---

Note: significant at the 10% level;  
numbers in brackets are the t-values.

Note: IND: Industrial market economies;  
UMI: Upper Middle-income economies;  
LMI: Lower Middle-income economies;  
LI: Low income economies;  
- numbers in brackets are the t-values of the difference in mean;  
- R means reject the null hypothesis that the means are equal;  
- A means accept the null hypothesis that the means are equal.

**II-G Manufacturing Sector (M)**

Tables II-1, II-2, II-9 and II-51 to II-66 reveal the following:

- (1) Out of the entire service sector, the manufacturing sector is more closely related to distributive services than other types of services. The values of DSBM and MFDS in Tables II-51 and II-59 are higher than other types of services.
- (2) Out of the entire service sector the manufacturing sector is the least related to social services in terms of input purchase (SSBM) and the least related to producer services in terms of output sales (MFRS).
- (3) The manufacturing sector depends quite largely on itself as the source of inputs and destination of sales. The Backward Dependency Ratio of the manufacturing sector on itself is 0.47 on average. The Sectorial Sales Ratio of manufacturing sector to itself is approximately 0.25. The Backward Dependency Ratio rises with the level of per capita income.
- (4) Although the manufacturing sector depends very little on producer services and personal services, this dependency starts to grow with the level of development. The ratios RSBM, ESBM, MFRS and MFES rise with the level of development. This is because as the level of industrialization increases, the demand for intermediate services also increases. This increase is stimulated by the process of specialization and the increased complexity of the economic system.

Table II-31 MANUFACTURING SECTOR

(I) Backward Dependency Ratio

(A) Service Sectors

RSBM =	0.013 + 0.595 x 10 <sup>-5</sup> x Y + 0.005D5 + 0.005D6 + 0.015D8 (0.95) (3.54) (0.61) (0.57) (1.52)	F = 12.88; R <sup>2</sup> = 0.71

II-H Backward, Forward and Total Linkages

The backward, forward and total linkages (Hirschman 1958) is a useful way to assess the impact of the manufacturing sector and service sectors on the economy at large. The backward linkage of sector  $j$  measures the total direct inputs of goods and services ( $BL_j = \sum_i A_{ij}$  where  $A_{ij}$  is the input-output coefficient). The forward linkage measures the total direct sales of goods and services of sector  $i$  to other sectors ( $FL_i = \sum_j A_{ij}$ ). The total linkage (the column sums of the Leontief inverse matrix  $(I-A)^{-1}$ ) measures the direct inputs and the indirect inputs in successive rounds. Inferences on total output and employment impacts of a certain sector can be drawn from the total linkages. Tables II-67 to II-76 report the values of these linkages of service sectors and manufacturing sector. Some salient features of these empirical findings are:

(1) The total linkage of the manufacturing sector is very large (the value is around 4.0). Among the service sectors, the Distributive Services have the largest total linkage (around 1.83).

(2) The total linkage of Personal Services rises with the level of industrialization. From Table II-67, the total linkage of manufacturing sector seems to rise with the level of development. However, this steady rise of the total linkage in the manufacturing sector is statistically weak as shown by the regression in Table II-68, II-1 and II-9.

(3) The forward linkage of producer services is the largest among the service sector (= 0.55) in fact, this magnitude is even larger than the forward linkage of the manufacturing sector (= 0.45). Social services have the weakest forward linkage. However, the impact of social services is definitely under-recorded because, most social services have the nature of public goods.

(4) The forward linkage of social services seems to rise with the level of development (Table II-8). This result is rather doubtful because of the amount of zero elements recorded in Table II-69. The t-test in Table II-70 also produces contradictory evidence.

Note: see Table II-4b .

(5) From Table II-69 and II-73 the forward linkage of the manufacturing sector (particularly the Agrofood and light industries) seems to rise with the level of development. However, (see the t-test in Table II-70 and the regressions in Table II-9) this relationship is statistically not very strong.

(6) The backward linkage of the manufacturing sector is very large (0.57 on the average). The backward linkage of personal services is the largest among the service sector (0.37).

### II-I Income elasticity of Demand of Manufacturing and Services

Many investigators (Clark 1957, Kuznets 1957 among others) have argued that the growth of the service sector and in post-industrial society is related to the high income elasticity of demand for services. The lower income elasticity of demand for manufacturing products is partly responsible for the decline of the manufacturing sector relative to the service sector. Our empirical investigations (Table II-77, II-78 and II-10) partially confirm this. The following observations are in order:

(1) In Table II-10, the average propensity to consume of manufacturing products and various services ( $C/GDP$ ) are regressed against per capita income and population. The t-values on per capita income is not significantly different from zero for all equations except the equation for producer services. The income per capita variable is then deleted (except of course for producer services) and the equations are retested. The F-test (not reported) shows that the new set regression equations are statistically identical to previous set of equations. This means, the average propensities to consume of manufacturing products, distributive services, personal services and social services are generally independent of per capita income. Hence, the income elasticities of demand must equal to one. Since the average propensity to consume of producer services varies positively with the level of per capita income, income elasticity of demand for producer services must be greater than one.

Table II-45 CONSUMPTION

Average Propensity to Consume (C/GDP) of:

(A) Manufacturing Sector:

$$CM/GDP = 0.46 + 0.0026\ln(Y) - 0.036\ln(N) - 0.10D5 - 0.096D6 - 0.11D8 \quad F = 3.16; R^2 = 0.44$$

(3.94) (0.16) (2.77) (2.33) (2.16) (2.34)

(B) Service Sectors:

$$CRS/GDP = 0.013 + 1.105 \times 10^{-5} \times Y + 5.12 \times N + 0.008D5 + 0.015D6 + 0.011D8 \quad F = 4.09; R^2 = 0.51$$

(0.78) (2.70) (0.90) (0.39) (0.73) (0.44)

$$CES/GDP = 0.097 + 0.758 \times 10^{-5} \times Y - 0.07D5 - 0.027D6 - 0.054D8 \quad F = 3.53; R^2 = 0.40$$

(5.06) (1.56) (2.95) (1.13) (1.85)

$$CSS/GDP = -0.05 + 0.0044\ln(Y) + 0.008\ln(N) + 0.013D5 + 0.007D6 + 0.026D8 \quad F = 3.34; R^2 = 0.46$$

(1.34) (0.87) (2.007)\* (0.97) (0.53) (1.76)

$$CDS/GDP = 0.036 + 0.012\ln(Y) + 0.021\ln(N) - 0.004D5 + 0.043D6 - 0.0005D8 \quad F = 2.14; * R^2 = 0.35$$

(0.86) (0.977) (2.06) (0.12) (1.30) (0.01)

---

Note: \* significant at the 10% level;  
numbers in brackets are t-values.

LMI VS LI	(+1.051,A)	(+1.012,A)	(+0.702,A)	(+1.085,A)	(+0.399,A)

Note: see Table II-4b

(2) The average propensity to consume of manufacturing products is around 0.27 for all the sampled nations. This is less than the average propensity to consume of services (i.e. the total of distributive, producer, personal and social services) which is around 0.39.

#### II-J Discussions

The linkage between the manufacturing sector and the service sectors (i.e. all of DS, RS, ES, and SS) are not very large. On the average, the Backward Dependency Ratio of the manufacturing sector on the (entire) service is approximately 0.17. The Sectorial Sales Ratio of the (entire) service sector to the manufacturing sector is approximately 0.13. Hence, the decline of the manufacturing sector in the Advanced Stage of industrialization probably does not affect the service sector very much.

The average propensity to consume of the manufacturing sector is around 0.27 and the average propensity to consume of the (entire) service sector is around 0.39. This shows that the impact of income induced demand on various sectors (the Engel's Law) as suggested by Kuznets (1957) and others must be significant.

Although the manufacturing sector is a declining sector at the Advanced Stage, it is still a very "influential" sector; the total linkage of the manufacturing sector is very high.

Among the various service sectors the distributive sector is the most "dependent" service sector on manufacturing products (i.e. the manufacturing sector is very important for DS). The producer service is the least "dependant" service sector on manufacturing products.

Conclusion

Part I of our empirical study supports the general patterns of development of the agricultural sector, manufacturing sector, other industrial sector and service sector, predicted in the literature (eg. Clark 1957, Kuznets 1957, etc.). We do not observe, however, that the service sector would "take-off" into rapid self-sustain growth in the Advanced Stage of development. This sector is growing but also at a slower rate above the national growth rate. One plausible explanation is from the linkage between manufacturing sector and the service sector. When the manufacturing sector contracts, the service sector should be affected as well.

Part II of the present study deals with the linkages between manufacturing sector and the service sector at various levels of disaggregation. The linkage between these two sectors is not very large. If the relationship was very large, the service sector would probably decline much more in the Advanced Stage of industrialization.

There is also some evidence that as industrialization advances, the demand for intermediate services also increases: this increase is due to the increased complexity and degree of specialization of the system.

The average propensities to consume of the manufacturing products and social services are very large. The income elasticity of demand for services is greater than one. These suggest that the Engel's Law type of explanation in the literature on the rise and fall of the service and manufacturing sectors is an important one.

Finally, the impact of the manufacturing sector on the rest of the economy is very large in spite of the fact that it is a declining sector in the Advanced Stage of industrialization. This is evident from the large magnitude of total linkage of the manufacturing sector.
