## 1. Introduction

Manufacturing is back - as a driving force of economic growth as well as in policy debates on the development of a country. Its relevance never diminished for developing countries. Industrialized countries, where contributions of manufacturing to the economy have consistently fallen in the last decades, have again come to realize the strategic importance of manufacturing in overall social and economic development. In 2010, the European Commission announced an *Integrated Industrial Policy for the Globalisation Era*<sup>1</sup>. The document stated that the financial and economic crisis has refocused attention on the central importance of a strong, competitive and diversified industrial manufacturing value chain for the EU's competitiveness and job creation potential. The communication sets out a strategic framework for a new integrated industrial policy that will stimulate economic recovery and jobs by ensuring a thriving world-class industrial base in the EU. One year later, the United States established the Office of Manufacturing Policy, which published a series of recommendations aimed at reinventing manufacturing in a way that ensures that U.S. competitiveness feeds into the nation's innovation economy and invigorates the domestic manufacturing base<sup>2</sup>. The new policy documents of industrialized countries emphasize the importance of manufacturing not merely in terms of production growth, but more importantly in terms of its innovative direction, its ability to create and supply new technology and its influence on growth and structural changes in other sectors of the economy.

Against the backdrop of renewed interest in manufacturing production, researchers have witnessed the emergence of a global manufacturing renaissance in different contexts with multiple emphases in scientific research as well as in white papers, which have been re-evaluating the importance of manufacturing since 2008. Prior to the onset of the recent economic recession, deindustrialization, loss of strategic manufacturing industries, increasing trade imbalances, decreasing technological dynamism and industrial competitiveness had been major concerns in industrialized economies. The financial freefall of 2008-2009 and the subsequent economic recession further fuelled concerns about the overall impact on national economies of an increasingly rapid process of deindustrialization. Since the onset of the crisis, there has been a substantial loss of jobs and a redistribution of manufacturing production globally with devastating effects on social welfare. Middle-income countries in the catch-up phase have witnessed a relative deceleration of their economies as a result of the contraction in global demand. Accordingly, many governments had to step in to rescue distressed

---

<sup>1</sup> European Commission: An Integrated Industrial Policy for the Globalisation Era, Brussels, 2010.

<sup>2</sup> Report to the President on Capturing domestic competitive advantage in advanced manufacturing, Executive Office of the President, White House, July 2012.

manufacturing firms and to protect national champions as well as to expand the monetary supply in an effort to counterbalance the credit crunch. The restructuring of the automotive industry and the subsequent efforts by various governments to reinforce domestic production are examples of this renewed scope for public action.

Meanwhile, governments of many developing countries began questioning the sustainability of a development model that focuses predominantly on the extraction of natural resources. Governments of middle income countries in particular have been concerned about the imbalance in the global distribution of production and trade in favour of a few emerging large economies. At the onset, the economic recession only had a mild effect on many developing countries, as there was no domestic determinant of recession. However, its impact gradually spread through commodity exchange, capital flow and labour migration. Due to reduced demand in the external market, the export of manufactured goods from developing countries fell consistently. Unfavourable conditions in the world market compounded with home-grown problems related to the cost of production, slow pace of technological endowment, fluctuating interest rates and inflation induced the decline of industrial production. Thus, deindustrialization has, to a certain degree, also taken place in developing economies.

Renewed interest in manufacturing has raised the expectation of many nations to change their course on the path of inclusive and sustainable industrial growth. It has redefined development models, incorporated new dimensions into industrial policy and addressed the challenges related to the impact of industrialization on the environment. These developments have created new opportunities and challenges for UNIDO as a world body dedicated to the promotion of industrialization. At a time when many governments are revisiting and reformulating their industrial plans and policies, UNIDO plays an indispensable role in assisting nations to define new strategies based on reliable empirical evidence. UNIDO maintains an international industrial statistics database and disseminates various statistical products worldwide. The statistical information made available by the organization offers a unique opportunity for countries to assess the current trends of world manufacturing, analyse the competitive industrial performance of nations and formulate new directions of industrial development.

The *International Yearbook of Industrial Statistics*, UNIDO's major statistical publication, is a compendium of detailed statistics on the level, structure and growth of world manufacturing. Based on data published in the *Yearbook* as well as on data available in the industrial statistics database maintained by UNIDO, the present report analyses manufacturing trends over the last two decades for the largest possible set of countries, namely nearly 200. The analysis documents the three most relevant stylized facts that characterize the last two decades. Firstly,

the positive relationship linking manufacturing value added per capita and gross domestic product per capita for different country groups; secondly, the process of redistribution of manufacturing value added across different countries and a set of country groups over the period under consideration, and finally, particular emphasis which is given to the two most striking facts underlying the transformation of the current manufacturing landscape: the profound manufacturing loss resulting from the global financial crisis and the strong acceleration the subsequent long wave of economic recession has impressed on the distribution of manufacturing production since 2008. The report presents estimates of the manufacturing loss by country groups and statistics on the different country performances.

## **2. Global manufacturing landscape**

The objective of this paper is to offer an overview of the current global manufacturing landscape based on manufacturing value added (MVA), a measure of a country's level of industrialization. To explore the importance of this indicator in an analysis of manufacturing development to determine the degree of industrialization and manufacturing trends across countries, familiarity with certain concepts is necessary. This section therefore introduces the approach developed by UNIDO for measuring manufacturing value added at the country level as well as for selecting different country comparators according to different country group criteria.

### **2.1 Manufacturing value added**

Manufacturing value added (MVA) of an economy is the total estimate of net output of all resident manufacturing activity units obtained by adding up outputs and subtracting intermediate inputs. Measurement of MVA requires appropriate demarcation of the type of economic activity and of the territory in which the activity takes place. The boundary of manufacturing as an economic activity is defined by the International Standard Industrial Classification of All Economic Activities (ISIC)<sup>3</sup>. In terms of territory, UNIDO Statistics uses the national account concept of resident units. Data are compiled for an economy rather than a country within its political boundary. Many territories function as a separate economy, occasionally with a different currency from that of the country they belong to in terms of political and administrative sovereignty.

---

<sup>3</sup> Revision 4 is the latest version of ISIC, which is being progressively introduced in national statistical systems around the world. There are regional (such as NACE in Europe and NAICS in North America) and national versions of ISIC which are largely compatible with ISIC.

UNIDO produces value added estimates of manufacturing activities at two levels – the sector level (often termed industry value added) and the aggregated level, referred to in this paper as manufacturing value added.

- i) The value added of a manufacturing industry (industry value added) is a survey concept that refers to the given industry's net output derived from the difference of gross output and intermediate consumption. Value added is calculated without deducing consumption of fixed assets represented by depreciation in economic accounting concepts. The social cost of producing value added is higher than that considered in the existing statistical practice, as it takes the depletion and degradation of natural resources into account.

Depending on the survey method selected, industry value added may often refer to census value added which disregards the margin between the receipt from and payment for non-industrial services. Survey data on industry value added may also disregard the contribution of small and household-based manufacturing units which are often excluded from the regular industrial survey programme. Estimates for such units are made separately for the compilation of national accounts. For these reasons, industry value added is used to measure the growth and structure, but not the level.

The UNIDO Industrial Statistics database presents industry value added at the 2-, 3- and 4-digit level of ISIC. This is the lowest possible industry group level which is, in many cases, almost equivalent to the product group. For example, at the 4-digit level of ISIC Revision 4, data are presented for 151 manufacturing industry groups.

Detailed description of UNIDO's databases INDSTAT2 and INDSTAT4 are provided on the statistics-related pages of UNIDO's website<sup>4</sup>.

- ii) The value added of the entire manufacturing sector (or MVA) is, theoretically, the sum of the value added of all manufacturing activities. However, in practice, MVA cannot simply be derived by adding up all industry value added figures because of the complexity associated with survey methods. Industry value added may not cover all activity units engaged in manufacturing due to the incomplete frame used in the survey. On the other hand, activity units are

---

<sup>4</sup> See [www.unido.org/statistics](http://www.unido.org/statistics)

often classified as manufacturing based on their primary activity. This implies that secondary activity can often be of a non-manufacturing nature. Such discrepancies are resolved in the process of compiling national accounts using supply use or input-output tables. Thus, MVA measures an exclusive and exhaustive contribution of manufacturing to GDP.

Statistics from INDSTAT databases are widely used to conduct analyses on structural change and demand supply balances. This paper analyses MVA as a measure of industrialization. Data for this purpose are taken from UNIDO's MVA database<sup>5</sup>.

While GDP provides an important point of reference for analysis of a country's overall economic development, it does not reveal any specific information about sectoral composition and, in particular, the different degrees of industrial development. Countries show profound structural differences which tend to relate to their stage of overall economic development and the difference contribution of the various sectors (agriculture, industry – and manufacturing as part of it – and services) their economic system is composed of. To capture the different levels of countries' industrial development, UNIDO generally uses manufacturing value added (MVA) per capita as the main indicator. In most cases, MVA per capita is used, i.e. a relative value of net manufacturing output to the population size, to measure a country's level of industrialization. The highly service-oriented offshore economies, which have achieved relatively high levels of overall income with a marginal contribution of manufacturing, are an exception.

One of the statistical uses of MVA per capita is classifying country groups according to stage of industrial development. While there is a common standard for country classifications by geographical region<sup>6</sup>, international agencies apply their own country groups that reflect their primary mandate in international development. The World Bank presents data based on gross national income per capita, i.e. three major income categories: low, middle and high income countries. These categories are based on the Bank's operational lending categories. The United Nation's Human Development Report (HDR) uses four country groups based on the human development index. The basic principle of UNIDO's country classification is to differentiate countries based on their stage of industrial development.

<sup>5</sup> MVA explorer.

<sup>6</sup> Standard geographical.

## 2.2 Country groups by stage of development

UNIDO's statistical and research publications have used MVA per capita to differentiate between country groups, however, this approach was not strictly followed due to the problem of a comparable valuation of output in different countries. At the level of an economy as a whole, countries' socio-economic performance can be compared based on GDP at purchasing power parity (PPP), which eliminates the difference between the nominal currency exchange rates and the actual prices of goods and services in different countries. PPP is based on the price of a basket of consumer goods derived from different types of economic activities, and serves as a composite factor of adjustment for exchange rates.

There is, however, no similar price comparator at the level of the manufacturing sector. Therefore, for the purpose of country classification, UNIDO uses an adjusted value of MVA per capita (at PPP), which is obtained as a product of two ratio variables:

$$\text{MVApc (adjusted)}_j = \text{GDP per capita (at PPP)}_j \times s_j ;$$

$$\text{where } s_j = \frac{\text{MVA}_j}{\text{GDP}_j}$$

MVApc (adjusted) is an implicit estimate of MVA per capita at PPP. This is the basic measure underlying the country groups in UNIDO statistics. It corresponds with the results of a UNIDO study which concludes that the share of MVA in GDP does not increase beyond a certain point once the country has reached its highest level of industrialization. GDP per capita at this point is estimated to be 13,000 international dollars (PPP)<sup>7</sup>. The share of MVA in GDP at this particular level of economic development is around 20 percent. Based on these figures, we conclude that an economy is considered 'industrialized' if its adjusted MVA per capita exceeds 2,500 international dollars (PPP).

UNIDO's country groups comprise two main categories: i) industrialized economies and ii) developing and emerging industrial economies. The basic criterion of this classification is MVA per capita. Additional measures were used to include very high-income economies—predominantly off-shore economies—in the group of industrialized economies. The group of developing and emerging industrial economies replaces the former group of developing countries. It consists of four sub-groups: i) emerging industrial economies, ii) China, iii) other developing economies, and iv) least developed countries (LDCs). Details on the country groups

---

<sup>7</sup> In Search of General Patterns of Manufacturing Development; Working Paper by Haraguchi & Rezonja; UNIDO, 2010.

used in UNIDO statistics are provided in a separate UNIDO publication as well as in the International Yearbook of Industrial Statistics.<sup>8</sup>

Country groups meet the following requirements of UNIDO's research and statistics activities:

- Setting up the modality of aggregation to monitor changes in the overall pattern of economic growth and structure;
- Enabling international comparisons to determine the leading regions and country groups and those lagging behind;
- Providing a basis for statistical analyses using basic and advanced methods, such as computation of mean value at the aggregated level, margin of variation, outlier detection and distribution pattern.

MVA per capita is a generalized measure. Provided that data is available, it would be more accurate to consider MVA in relation to the total number of employees or, better yet, to the total number of hours worked (UNIDO, 2010). Such a measure would allow us to identify possible inequalities with reference to industrial development on a global scale; possible centres of industrialization (or lack thereof) might be useful for decisions on international aid or other forms of economic cooperation. The production and technological capabilities of countries at different stages of economic development vary. The technologies countries employ in production differ as do their leading industries. This makes country comparability difficult and suggests the need to benchmark countries that are at the same stage of development, in other words, those countries that tend to have similar production/technological structures.

Grouping countries according to their MVA per capita is not the only way to analyse countries' industrial development. Countries could also be grouped using cluster analysis techniques or simply selecting other development indicators. The number of comparators is actually of less importance than the selection criteria adopted. As highlighted in the IDR 2005: "There is no optimal number of comparators, and different countries may be used different purposes. A large number of comparators from across the world may be used (assuming that the data is readily available) to assess performance for broad issues like MVA or export performance, technology structures or inward FDI. A smaller set may be used to assess other variables like skill formation, R&D or risk ratings" (UNIDO, 2005: 9). A classification based on MVA per capita is not the only method applied in UNIDO statistics. UNIDO also groups countries by 'income category' like the World Bank as well as into 'special groups'.

---

<sup>8</sup> UNIDO, *International Yearbook of Industrial Statistics*, 2013, Edward Elgar, UK.

The country groups have a regional dimension as well. A regional distribution of MVA makes a focus on the industrial development of countries in a specific geographic area possible. This is of particular interest for countries seeking to benchmark their ‘local’ industrial development and, specifically, to identify comparable countries in their regional area or continent. Regional comparisons also provide information on inequalities within and across regions in the world.

Thus, UNIDO Statistics’ new country groups reflect countries’ stage of industrialization, geographic region and income category. The country groups also include special groups of interest for data users. In this report, we use the first country group based on stage of industrialization, although disaggregated figures are presented so that ad hoc analyses based on geographical or income comparators can also be conducted.

### **3. World manufacturing growth – Empirical evidence**

Since the onset of the 2009 crisis, there has been a proliferation of policy reports, academic contributions, national manufacturing strategies and white papers in all major industrialized economies investigating whether manufacturing still matters<sup>9</sup>. After having lost 41 percent of its manufacturing jobs within 30 years, the U.S. today is among the most active players in shaping a *new pro-manufacturing vision* (see Andreoni and Gregory, 2013). This is rooted in the following key arguments:

- (i) Manufacturing is the main engine of economic growth due to its *higher productivity* and *scope for innovation*.
- (ii) Manufacturing is a crucial source of *high quality employment* (in the period 2008-2010, it was estimated that earnings in manufacturing in the U.S. were around 20 percent higher than earnings in non-manufacturing industries (see Helper et al., 2012)).
- (iii) Producing tradable manufactured goods is essential for maintaining the *trade balance*, given that around two-thirds of world trade is still in manufactured goods (according to UN COMTRADE, this figure was 83.4 percent in 1996, while in 2009, it was 77.4 percent, of which 38 percent was in medium-tech products).

Many of the rationales put forward resemble earlier thinking on industrial growth theory, although they are often supported by new empirical evidence. For example, Rodrik (2009) reports that since 1960, economic growth in developing countries has been strongly associated with the development of modern industrial sectors (both manufacturing industries and agribusiness). Another recent empirical analysis confirms the ‘engine of growth hypothesis’ for

---

<sup>9</sup> See, among others, Tasse, 2010; Pisano and Shy, 2009; Bianchi and Labory, 2011.

a sample of 90 countries (21 advanced economies and 69 developing countries) in the period 1950-2005 (Szirmai and Verspagen, 2010). The study shows that the share of manufacturing is positively correlated with economic growth from 1950 to 2005 (in particular, for poorer countries), while services had a significant positive effect only until 1990, with coefficients far lower than those of manufacturing. Interestingly, in the period 1990-2005, the coefficient for services became insignificant.

### **3.1 Growth pattern by country groups**

The present report provides new empirical evidence on the relationship between manufacturing value added (MVA) per capita and the gross domestic product (GDP) per capita by country group. A discussion of the relationship between these two variables is important in that if there is a clearly distinguishable trend, for example, between increasing levels of MVA per capita and of GDP per capita, the implication is that more economic growth leads to increased industrialization and vice versa. Taking MVA per capita (constant price) as an independent and GDP per capita (constant price) as a dependent variable, we obtain a model of order two. An overall positive relationship can be recorded when investigating the graphical output on the facing page, revealing how the growth of GDP per capita goes hand in hand with increases in MVA per capita. Apart from that, a number of distinctive key features can be observed when we analyse the relationship between GDP and MVA per capita by introducing a distinction among different country groups. The graphical output of such a model is illustrated in Figure 1.

The curve that represents industrialized countries (INDs) exhibits the highest overall MVA per capita level and has the strongest tendency of saturation. That is, economically advanced countries are those with the highest level of industrial development. For this group of countries, the slow-down of MVA contribution to overall income is particularly notable and is reflected in the downturn of its corresponding curve.

The LDCs' curve evolves along the lowest path of industrial development: not only do these countries report the lowest MVA and GDP values; they also rank last when it comes to MVA contribution to country-group income. For example, at an income level of USD 403, LDCs report much lower MVA values than other developing countries (ODCs) or emerging industrial economies (EIEs)<sup>10</sup>. Apart from the relatively poor general performance in comparison to the other three aggregates, a general slowdown of MVA contribution to GDP is recorded for LDCs. Even though the same dynamics can be observed for the IND aggregate, this process of

---

<sup>10</sup> The adoption of an exponential scale partially reduces this effect visually.

saturation takes place at a much earlier stage in LDCs, indicating a weaker influence of manufacturing on overall economic development.

**Figure 1** MVA per capita vs. GDP per capita (constant prices)

Source: UNIDO Statistics, 2013

Overall, the aggregates of EIEs and ODCs show comparable dynamics, however, their development path differs with respect to their slope. A higher manufacturing value added contribution for any given income per capita (GDP) level can be recorded for the aggregate of EIEs. Yet, neither aggregate shows any signs of stagnation or saturation. We can therefore conclude that manufacturing remains an important source of growth and driver of economic development for these countries.

When looking at the shape of the curves for the EIEs and ODCs, it remains unclear whether one, both or none of these two aggregates will follow a path that is similar to the one recorded for the IND aggregate. This is attributable to the fact that despite showing highly positive dynamics, they have not yet reached the level at which the slowdown in MVA contribution to overall GDP can be recorded for the aggregate of INDs.

Taking the median MVA per capita and GDP per capita for 2012 into account, we divide the world into four quadrants as shown in the table below:

<p><b>Quadrant I</b> MVA &lt; median GDP &lt; median</p>	<p><b>Quadrant II</b> MVA &gt; median GDP &lt; median</p>
<p><b>Quadrant III</b> MVA &gt; median GDP &gt; median</p>	<p><b>Quadrant IV</b> MVA &lt; median GDP &gt; median</p>

The first quadrant represents countries that are lagging behind in terms of industrial and economic growth. Both the MVA and GDP per capita values in this quadrant are below the median. The industrial base of these countries is relatively weak, which has prevented them from achieving higher levels of economic growth. Countries in the second quadrant with an MVA per capita above and a GDP per capita below the median represent the considerable weight of the manufacturing sector for development. These countries have developed a strong industrial base whose economic growth potential has not yet fully unfolded. The third quadrant with an MVA and GDP per capita above the median denotes the highest level of manufacturing activity as well as of overall economic development. Industrialization has accorded these countries a high level of economic development. Countries with an MVA per capita below and a GDP per capita above the median are concentrated in the fourth quadrant, indicating that overall GDP is more dependent on other sectors than on manufacturing. The countries within each quadrant are listed in Table 1.

Several developing countries, especially those of the group of LDCs, fall into “Quadrant I” of the table, implying that their economy is characterized by a low level of industrialization.

When looking at the figures of the countries in the second quadrant, we find that they have a relatively high share of manufacturing value added in GDP (see also Figure 1). Three important Asian countries in this quadrant are China, Indonesia and Thailand. These countries have achieved a significant level of industrialization while their level of overall economic development still lies below the median level. For example, following the 2009 crisis, the increase in manufacturing output in Indonesia—now the largest economy in Southeast Asia among this group—was the key driver of growth in the country’s economy. The third quadrant

mainly includes industrialized and emerging industrial economies (see Table 1), which benefit from both high levels of manufacturing activity and wealth. Among these countries are manufacturing leaders such as the U.S., Japan, Germany and the Republic of Korea. The fourth quarter includes countries that are more dependent on other sectors and less so on manufacturing. For instance, the Maldives' major economic activity is tourism; Jamaica's economy is heavily dependent on services, which accounts for more than half of its GDP. Other economies in this quadrant with a relatively high GDP per capita, such as Botswana or Equatorial Guinea, are more dependent on their natural resources.

**Table 1 List of countries by quadrant**

<b>Quadrant I</b>		<b>Quadrant III</b>	
Afghanistan	Madagascar	Andorra	Libya
Algeria	Malawi	Argentina	Liechtenstein
Angola	Mali	Aruba	Lithuania
Armenia	Marshall Islands	Australia	Luxembourg
Azerbaijan	Mauritania	Austria	Malaysia

China	Thailand	Cuba	Montenegro
El Salvador	Macedonia	Dominica	Palau
Fiji	Tunisia	Equatorial Guinea	Panama
Guatemala	Ukraine	Gabon	Saint Lucia
Indonesia		Grenada	St Vincent and the Grenadines

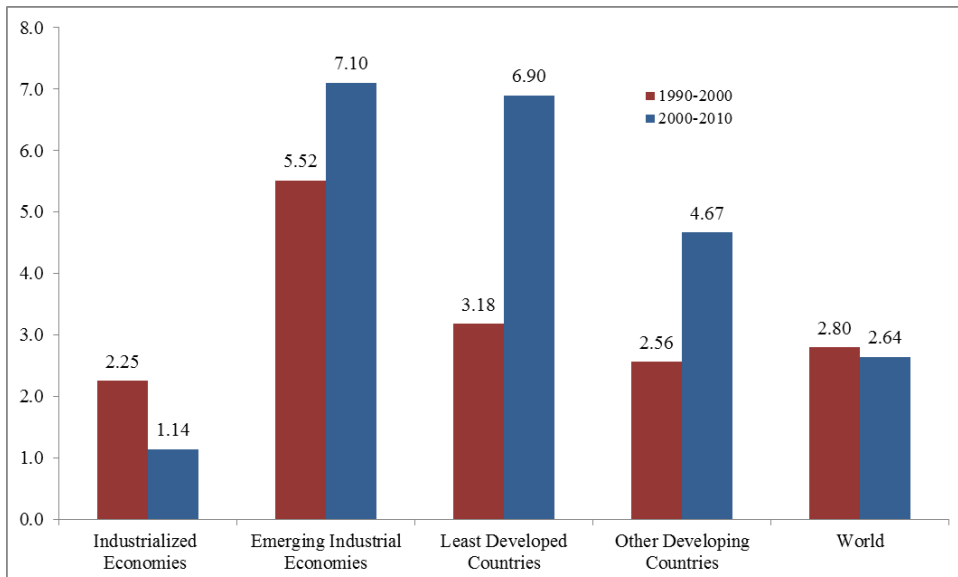

The large number of countries in the first and fourth quadrant reflects the strong correlation between MVA and GDP per capita, which supports the conclusions drawn from the model in Figure 1.

### 3.2 Recent manufacturing growth figures

Global manufacturing has, over the last two decades, been characterized by a significantly higher pace of growth in developing countries compared to industrialized countries, which is generally explained by domestic and external factors. The low production base, abundance of locally produced raw materials and increasing surplus labour force, domestic investment and pro-growth government policies served as major domestic factors of the expansion of manufacturing in developing countries. The determinant external factors included foreign direct investment together with a strong wave of outsourcing production activities by companies based in industrialized countries and favourable conditions in international trade. By contrast, manufacturing growth slowed in industrialized countries for three reasons. First, growth has slowed considerably as a result of market saturation. Second, the location of production has shifted to developing countries, Third, as income grew, the service sector expanded tremendously and claimed a higher stake in the economy, squeezing the share of manufacturing.

Measurement issues also affect manufacturing growth figures in industrialized economies. As a result of the so-called ‘unbundling’ of the manufacturing process, several types of services which were considered incidental to manufacturing in the past, began to be categorized as primarily service activities. This includes research and design, warehousing and transportation of manufacturing goods as well as ICT-related services.

**Figure 2** Average annual MVA growth rate (in %)

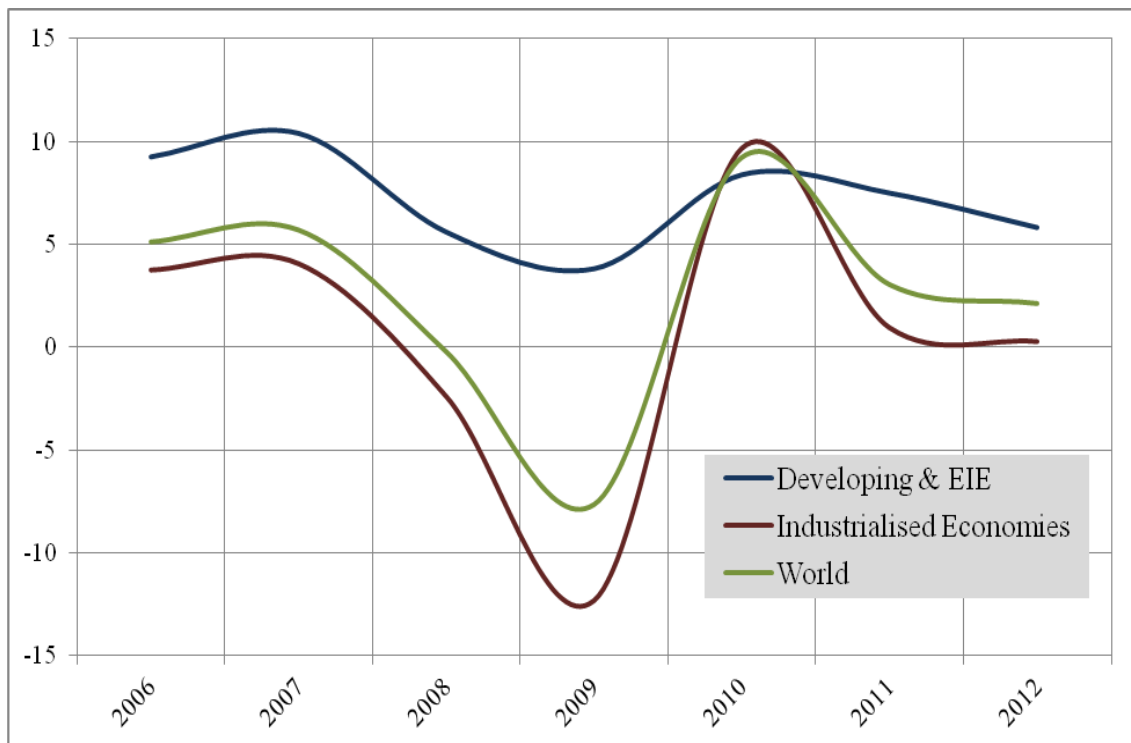

The growth figures for manufacturing products in developing countries have remained quite high in the last two decades, which significantly increased exports from developing countries. Although the share of local value addition was relatively low in the production of export-

oriented goods, the expansion of industrial activities had a huge impact on employment generation, household income and consumption expenditure. Figure 2 provides an overview of the average annual MVA growth rate for a comparison of the last two decades.

The graph illustrates that the manufacturing growth rate significantly accelerated in developing and emerging industrial economies. The average annual growth of emerging industrial economies rose to 7.1 percent in 2000-2010 compared to 1990-2000. The change was even more obvious among LDCs, where average annual growth of MVA doubled in the last decade compared to 1990-2000. This higher growth rate was achieved despite the fact that growth in these countries was relatively lower in the years following the onset of the financial crisis in 2008. For industrialized economies, the trend was reversed, reflecting the effects of crises and saturation on the manufacturing sector.

**Figure 3** Estimated annual growth rates of world MVA by years

While the average growth over two decades indicates a positive trend for all economies, a closer look at recent years reveals the grave effects of the financial crisis on manufacturing growth of industrialized countries. As illustrated in Figure 3, the annual growth rates of world MVA dropped considerably in 2008-2009. The crisis hit industrialized economies hard, with decline in production up by about 13 percent. Production reached its lowest level in 2009. The effect of the crisis was fairly mild on developing economies at the onset. However, due to the protracted recession in industrialized countries, exports from developing economies decreased and capital

inflow fell. The impact of these changes on developing economies became more visible after 2011.

The figure suggests that the recession continued to affect manufacturing growth of industrialized countries well beyond 2009. After a period of recovery in 2010, the recession took hold in all country groups. The growth rate began slowing down in 2011 and continued to decelerate in 2012. The instability in the financial markets and government interventions with austerity measures further affected the growth of European industrialized economies with significant job losses, a drop in household income and, consequently, further declines in production.

The next section presents some estimates of the loss in world MVA attributable to the financial crisis.

### **3.3 Leading manufacturing economies**

MVA constitutes the base indicator to determine a country's stage, degree and level of industrialization. Hence, MVA is used to benchmark countries' position in the world manufacturing landscape and to track countries' industrialization trajectories. This section presents a benchmarking exercise for leading manufacturing economies in 2012. The table presents MVA data for 183 countries reported in the *International Yearbook of Industrial Statistics*.

Since manufacturing output is a major indicator of industrial performance, the leading manufacturing economies have been identified as the top 15 contributors to world manufacturing value added in 2012 as well as in 2002. As shown in Figure 4, the top 15 manufacturing countries generate nearly 80 percent of manufacturing value added in the world, while more than 60 percent is concentrated in the three leading manufacturers, namely the U.S., China and Japan. During the decade examined here, China witnessed considerable growth in manufacturing value added, doubling its contribution to world MVA. Similarly, the Republic of Korea, India and Turkey also improved their share in world MVA. Five major economies from Europe are among the top 15, with a combined contribution to world MVA of 16 percent in 2012, down from 23 percent in 2002. Within this decade, the Republic of Korea emerged as a fully industrialized country; in 2002, it was still considered a developing economy. Five economies among the top 15, namely Brazil, China, India, Mexico and Turkey, are not yet included in the group of industrialized countries.

**Figure 4** Top 15 countries by share in world MVA (in %), at constant 2005 prices

The determining role of manufacturing in economic growth (see section 2.3) is reflected in the fact that 14 out of the 15 leading manufacturing economies are also present in the ranking of the top 15 contributors to world GDP. The three exceptions, Switzerland, Singapore and Netherlands, do not appear in the top 15 leading manufacturing economies only due to their size and despite their MVA per capita (ranked 2<sup>nd</sup>, 4<sup>th</sup> and 15<sup>th</sup>, respectively, in the world). Taken together, the 14 leading manufacturing economies contributed 77 percent of world GDP in 2012, their ranking closely reflecting that in Figure 2 (see also Table A1), at least for the first group of countries at a more similar stage of industrial development (China is the obvious exception, while the United Kingdom's jump in the GDP ranking is the result of its relatively strong service sector).

In Table A1, the selected countries are ranked in terms of total MVA for 2012 as well as MVA per capita. Data on MVA per capita and share of MVA in world MVA are presented for each country. The share each country contributes to world GDP is reported as well. The presentation of the full set of output indicators allows an interpretation of the ranking irrespective of any distortive effects attributable to country size in terms of population or to stage of economic development, as generally reflected by the share of MVA in total GDP. For example, large countries with high population density and high internal demand tend to underperform in terms of their MVA per capita, while their share of MVA in total GDP tends to decline at advanced

stages of economic development, measured by GDP per capita (Japan and Germany are exceptions in this respect). In a sectoral comparison for two reference years, 2005 and 2011, the sectoral share in total MVA reveals that the U.S. and China lead in most manufacturing industries. Japan held a leading position in the production of motor vehicles with a share of 22 percent and 23 percent<sup>11</sup> of world production in the years 2005 and 2011, respectively. Among developing and emerging industrial economies, Mexico is a major producer of food and beverages, with a 20 percent and 17 percent share in the total MVA of developing countries and EIEs in 2005 and 2011, respectively. Leading Mexican brands have well-developed national distribution networks and are well positioned in the market. They enjoy high brand awareness among consumers, who are very loyal despite economic variations. The U.S. had a 24 percent and 21 percent share of world total value added in the food and beverages industry in 2005 and 2011, respectively.

Among developing and emerging industrial economies, the top five leading countries in textiles in 2011 were China, India, Turkey, Indonesia and Pakistan. Turkey moved from second place in 2005 to third in the production of textiles in 2011, attributable to an increase in the competitiveness of other countries. The textiles industry in Pakistan is the economy's mainstay and despite the drastic changes that have taken place in the manufacturing pattern over the years, the textiles industry continues to be the major employer of Pakistan's industrial labour force.

In wearing apparel, China, Italy and the U.S. were the leading countries in both 2005 and 2011, while Turkey was the leading country in the manufacture of wearing apparel in the markets of developing countries and EIEs. Mexico, India and Brazil led the ranks in the production of chemicals and chemical products in the reference years among developing countries and EIEs. The U.S. moved from being the top non-metallic producer with 18 percent of world total MVA to second place in 2011, while China replaced the U.S. with a 24 percent contribution to world total VA owing to the tremendous progress China has made in technology use.

---

<sup>11</sup> All shares are based on 2005 constant prices.

**Table 2 Manufacturing leaders in selected industries (2005, 2011)**

Industrial activity	2005		2011	
	Country	Share <sup>a)</sup>	Country	Share
Food and beverages	United States of America	24	United States of America	20.9
Tobacco products	United States of America	27.3	China	41.6
Textiles	China	21.2	China	46.1
Wearing apparel	China	21.5	China	47.4
Leather products and footwear	China	22.6	China	48.9
Wood products	United States of America	25.7	China	17.9
Paper and paper products	United States of America	27.7	China	24.8
Printing and publishing	United States of America	18	United States of America	13.4
Coke, refined petroleum products, nuclear fuel	United States of America	30.1	United States of America	22.3
Chemical products	United States of America	29.3	United States of America	22.9
Rubber and plastic products	United States of America	23.4	United States of America	17.5
Non-metallic mineral products	United States of America	17.8	China	23.9
Basic metals	China	20.9	China	55.3
Fabricated metal products	United States of America	22.5	United States of America	17
Machinery and equipment n.e.c	United States of America	20	China	23.3
Office, accounting and computing machinery	United States of America	27	China	38.8
Electrical machinery and apparatus	United States of America	18.8	China	28.6
Communication equipment	Japan	20.5	China	21.8
Medical, precision and optical instruments	United States of America	41.6	United States of America	38
Motor vehicles, trailers, semi-trailers	Japan	21.7	Japan	23.3
Other transport equipment	United States of America	34.9	United States of America	28.2
Furniture; manufacturing n.e.c.	United States of America	29.5	United States of America	23.8

a) In world total value added at constant prices.

In machinery and equipment, the U.S. dropped from first to fourth position, being surpassed by China, Japan and Germany in both product and process technology. India and Brazil are major producers of machinery and equipment among the developing countries and EIEs. The contribution of Japan to the global total value added of radio, television and communication equipment declined from 21 percent in 2005 to 16 percent in 2011. China and the U.S. are leaders in the industry.

The U.S. ranks first by a significant margin in medical, precision and optical instruments as the world's largest producer.

As noted above, Japan is the top manufacturer of motor vehicles in the world with a share of 22 percent and 23 percent in total activity value added in 2005 and 2011, respectively. China's automobile industry has continued to expand despite the global economic downturn. China surpassed Germany and the U.S. after 2005 to become the second-largest automobile producer in 2011. Mexico, Brazil and India are the major producers of motor vehicles in the group of developing countries and EIEs.

The contribution of industries to world MVA confirms the fact that industrialized countries perform better in high-technology industries while developing and emerging industrial economies perform well in the production of basic consumer goods

In accordance with the figures, the change in pattern of world MVA in ISIC industries from 2005 to 2011 shows that the role of developing and emerging industrial economies is becoming more significant in all economic activities. In 2011, more countries from this group more effectively contributed to the various markets compared to the year 2005, while industrialized countries experienced a decline in the share of total value added in manufacturing industries, perhaps due to saturation in economic development.

#### **4. Changing scenario of world manufacturing, 1990 – 2010**

After having provided a snapshot of the current global manufacturing landscape, this section of the report takes a dynamic perspective by focusing on changes in the distribution of MVA per capita at the *global level, across country groups and in selected countries* over the last two decades. The timeframe considered is 1990 – 2010, although three data points are adopted for the analysis: 1990, 2000 and 2010. The final section also provides a snapshot of the impact of such changes in the global distribution of manufacturing on other variables.

#### **4.1 Changes in the global distribution of manufacturing value added**

From a global point of view, Figure 5 shows the distribution of MVA per capita in the years 1990, 2000 and 2010 for all countries. The figure shows an uneven distribution of manufacturing output among countries and resulting variations of the overall level of industrialization. Manufacturing output is not at all equally distributed and remained so over the last two decades, albeit some changes were registered. Some countries are characterized by very high levels of industrialization proxied by a very high MVA per capita, while the majority of countries in the same time period did not pass an MVA per capita threshold of USD 2,000. However, the skewness of the distribution curve actually increased from 1990 to 2000, but decreased considerably from 3.4 to 2.35 between 2000 and 2010. This indicates that the level of industrialization was more equally distributed on the global scale in this last decade than in the previous one. The most obvious explanation for this change in the manufacturing distribution curve in this last decade relates to the structural impact of the financial crisis on MVA data (this analysis is further developed in section 3.3). However, it seems that broader transformations in the global manufacturing landscape are responsible for such shifts. If we take a closer look at the data (see Tables A2, A3 and A4 in the appendix), we detect the following patterns:

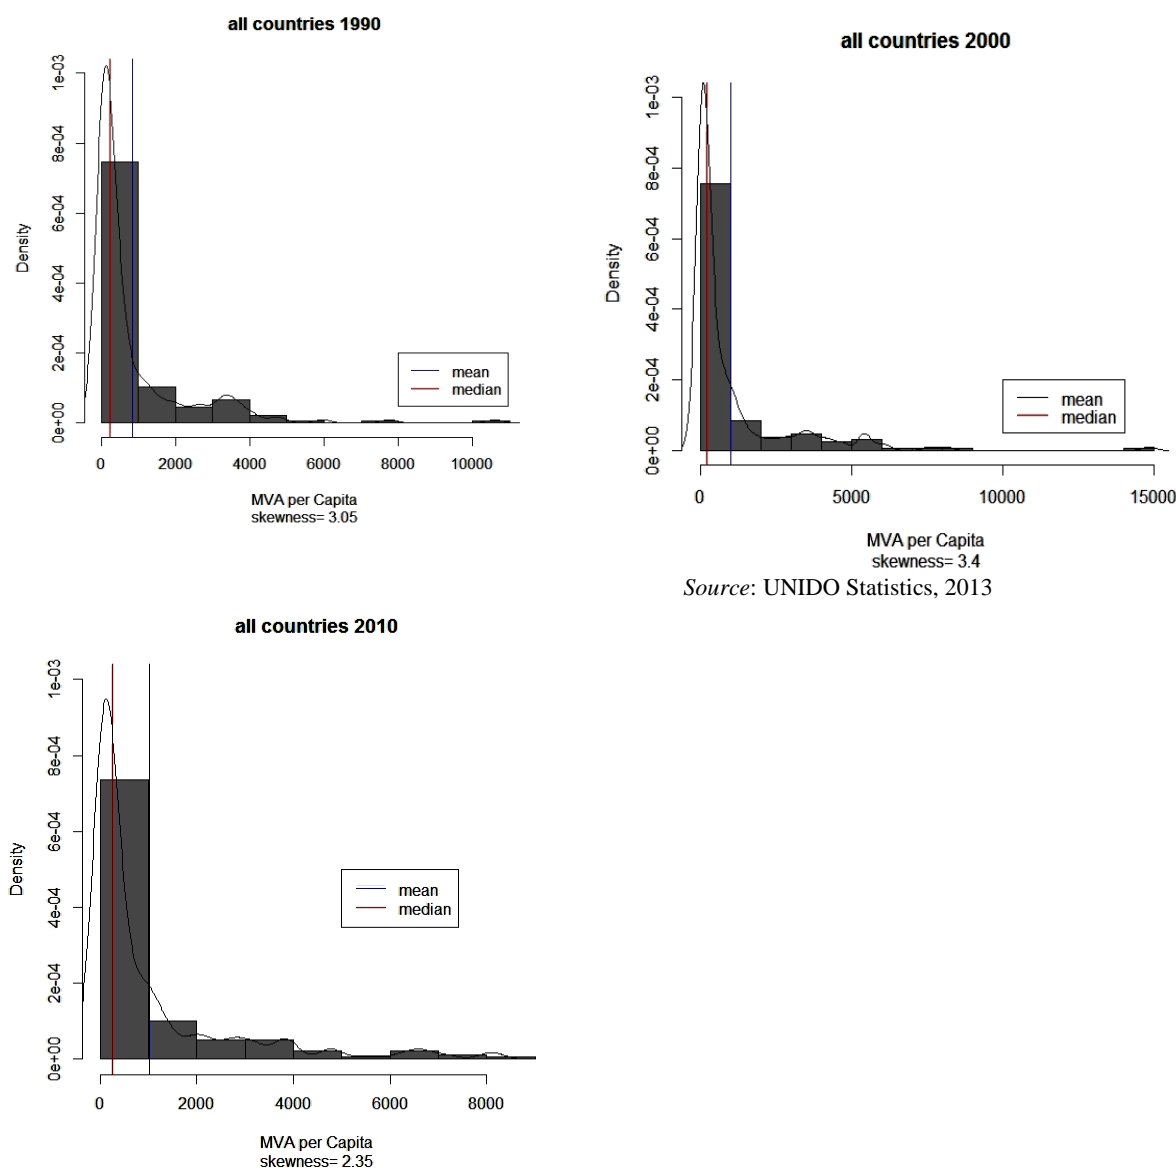

Considering the median MVA per capita in the year 1990 (USD 208), 100 countries in the world had an MVA per capita below this figure. In 2000, this number of countries declined to 96, indicating a slight growth in manufacturing output. In the year 2010, the MVA per capita of 69 of the countries remained below the median MVA per capita. In other words, compared to 1990, 31 countries attained a higher level of industrialization, while the median MVA per capita shifted to USD 497.

In the year 1990, 151 countries registered an MVA per capita below USD 1,000. This number of countries had not changed significantly by the year 2010, but had declined to 125 in 2010, which reflects growth in the level of industrialization primarily in developing countries and emerging industrial markets. Fifteen countries had an MVA per capita of between USD 1,000 and 2,000 in the year 1990. This figure remained unchanged in the year 2000, but increased to 27 countries by the year 2010, indicating the growth in countries benefiting from manufacturing activities.

In 1990, 32 countries had an MVA per capita higher than USD 2,000 of which 13 registered an MVA per capita higher than USD 5,000. As can be seen in Figure 5, the distribution changed in 2010 and became less skewed. The number of countries with an MVA per capita above USD 2,000 increased to 46 countries.

World MVA per capita in 1990 was USD 871, with the group of industrial economies leading with an MVA per capita equal to USD 3,555 in contrast to USD 181 of developing and emerging industrial economies. In 2000, world MVA per capita increased to USD 957; the figures for industrialized economies and developing and emerging industrial economies also increased to USD 4,044 and USD 242, respectively. By 2010, world MVA per capita had increased considerably to USD 1,466, with industrialized economies registering an MVA per capita of USD 5,151 and the manufacturing output of developing and emerging industrial economies grew remarkably and registered an MVA per capita of USD 671, nearly four times higher than the figure recorded for 1990. From the figures it can be inferred that the picture changed dramatically over the last decade. The change in pattern is becoming more obvious as is the fact that manufacturing value added is growing all around the world.

**Figure 5** Distribution of MVA per capita in the world for 1990, 2000 and 2010

To sum up, the overall the distribution of MVA per capita is not normal and is strongly positively skewed, i.e. with relatively few high MVA per capita values. Furthermore, the non-normality of the global MVA per capita distribution did not significantly improve during 1990-2010.

The above analysis takes a global perspective on manufacturing distribution while it does not take countries' individual trajectories and their movement across manufacturing distribution into account. In other words, countries may vary within the distribution intervals as well.

On the other hand, as discussed above and shown in Table A5, only a limited number of countries experienced an increase (or decrease) in their MVA per capita that was sufficient to generate a shift in the manufacturing distribution curve, at least in the first decade. If we consider countries that had an MVA per capita above USD 2,000 in 1990, only 4 of 38 countries registered a decrease in MVA per capita from 1990 to 2000, while all other countries witnessed an increase. In the second decade, from 2000 to 2010, the number of countries at the top of the distribution curve with a significant decrease in MVA performance was much higher, while a few outliers like China, the Republic of Korea, Ireland, Poland and Malaysia managed to climb the ladder, registering three-digit increases in MVA per capita performance. This pattern indicates that a country's MVA per capita increase can slow down after the economy reaches a high level of industrialization. Table 3 was extracted from Table A5 in the appendix to discern those 25 countries that registered both the best and the worst performances in improving their MVA per capita over the decade 1990-2000 and 2000-2010. The variation in countries' MVA is calculated by subtracting the MVA value at the end of the decade from the corresponding value in the starting year for each country. Countries with a positive variation in MVA are considered 'runners' and those with a negative growth compared to the beginning of the decade are classified in the so-called 'loser' economies subset.

In 1990-2000, Ireland, Malaysia, Poland and the Republic of Korea registered a high increase in MVA per capita on account of a strong growth performance in production and exports of manufactured goods. During this period, Malaysia and the Republic of Korea moved from the category developing economy to that of fully industrialized economy. A boost in production of communication equipment and other electronics provided Finland, Singapore and Sweden a significant increase in MVA per capita. The U.S., Canada, Italy, France and other leading industrialized economies also achieved significant increases in manufacturing output. By contrast, several countries of Eastern Europe and former Soviet Republics faced a sharp decline in manufacturing output as a result of the Soviet Union's collapse. MVA per capita fell in

Albania, Bulgaria and Romania. MVA per capita dropped by 87 percent in Azerbaijan, 75 percent in Georgia, 60 percent in Ukraine and nearly 40 percent in the Russian Federation.

In the last decade, from 2000 to 2010, the declining growth trend in Eastern European countries and the former Soviet Republics reversed sharply. Among the countries with an impressive growth performance were Belarus, Estonia and Romania. The major Asian manufacturers Japan and the Republic of Korea continued to maintain their growth in MVA per capita in 2000-2010. Despite having the highest population in the world, China made remarkable achievements by increasing its MVA per capita by 1.7 times within 10 years. By contrast, MVA per capita dropped in some of the major industrialized countries such as Canada, Italy, Spain and the United Kingdom. This development shifted the centre of the gravity of industrial growth from Europe/North America to East Asia.

<b>Country groups:</b>							
Industrialized Economies				Other Developing Countries (ODCs)			
Emerging Industrial Economies (EIEs)				Least Developed Countries (LDCs)			

Source: UNIDO Statistics, 2013

Table A5 in the appendix presents all variations in MVA per capita for each country from 1990 to 2000 and from 2000 to 2010. Table A5 also ranks countries by MVA per capita in 2010 and clusters them according to their respective country group, namely: industrialized economies, emerging industrial economies, other developing countries and least developed countries.

#### **4.2 Changes in the distribution of manufacturing value added within country groups**

To obtain a more visible structure of world manufacturing, data have so far been analysed across country groups. This section examines changes in the distribution of MVA per capita *within* each country group over the last two decades in order to obtain a clearer picture of the development of the composition of MVA over the last two decades.

##### ***Industrialized countries***

More homogeneity in the level of industrialization within the group of industrialized countries can be expected. This is based on the assumption that all countries in this group have already attained a very high level of industrialization. Therefore, the difference in value added is likely to have a proportionately smaller impact on the industries of the respective economies. Figure 6 illustrates the distribution of MVA in the group of industrialized countries. All the histograms are slightly skewed to the right. There is no major difference between the share of MVA per capita in 1990 and in 2000; the distribution and peaks are almost the same (with a slight increase in the mean and median moving from around 2,500 to 3,000). On the contrary, the histogram for 2010 showed a significant increase in the skewness of density and a concentration of two sub-groups of countries, those with an MVA per capita between USD 2,000 and 4,000 and between USD 4,000 and 6,000.

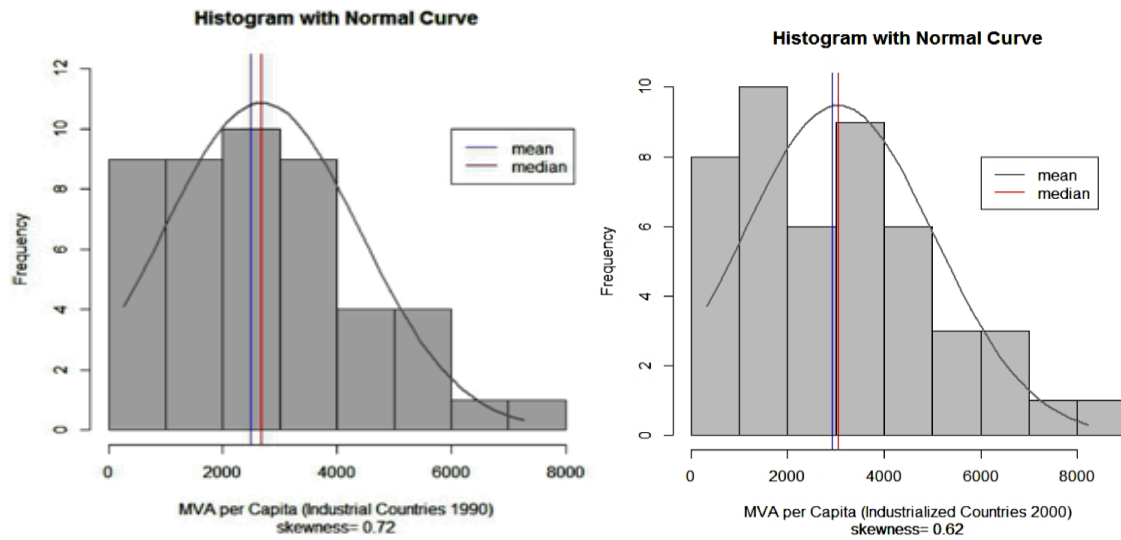

Graphs of kernel density estimates (see below) illustrate that the MVA distribution for 1990 and 2000 could be a mixture. The corresponding kernel densities both have two peaks (blue and red curves) which show the mixture of the two distributions. The latter could be interpreted as two sub-country groups within this group. The kernel density for 2010 (yellow curve) illustrates that those two subgroups were merged into one and that the density became uni-modal and closer to a normality-shaped density during the second decade. As a result, the share of MVA became more uniformly distributed within the group of industrialized countries. The density is slightly skewed to the right due to the high concentration of MVA per capita within the interval from USD 2,000 to 6,000.

Table A5 offers insights about the main drivers of the changes in the distribution of MVA per capita within the group of industrialized countries. While countries within this group recorded

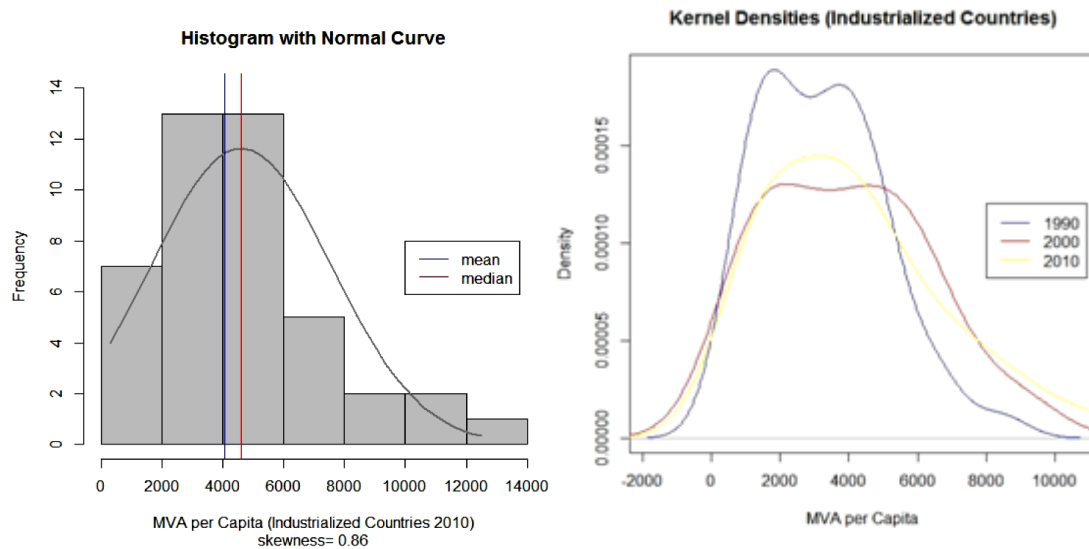

an increase in MVA per capita during the first decade with virtually no exception, a number of industrialized countries (in particular Italy, United Kingdom and Spain) fell behind in the distribution during the second decade.

**Figure 6** Distribution of MVA per capita in industrialized countries

(To reflect the main body of the distribution, some outliers are omitted)

Source: UNIDO Statistics, 2013

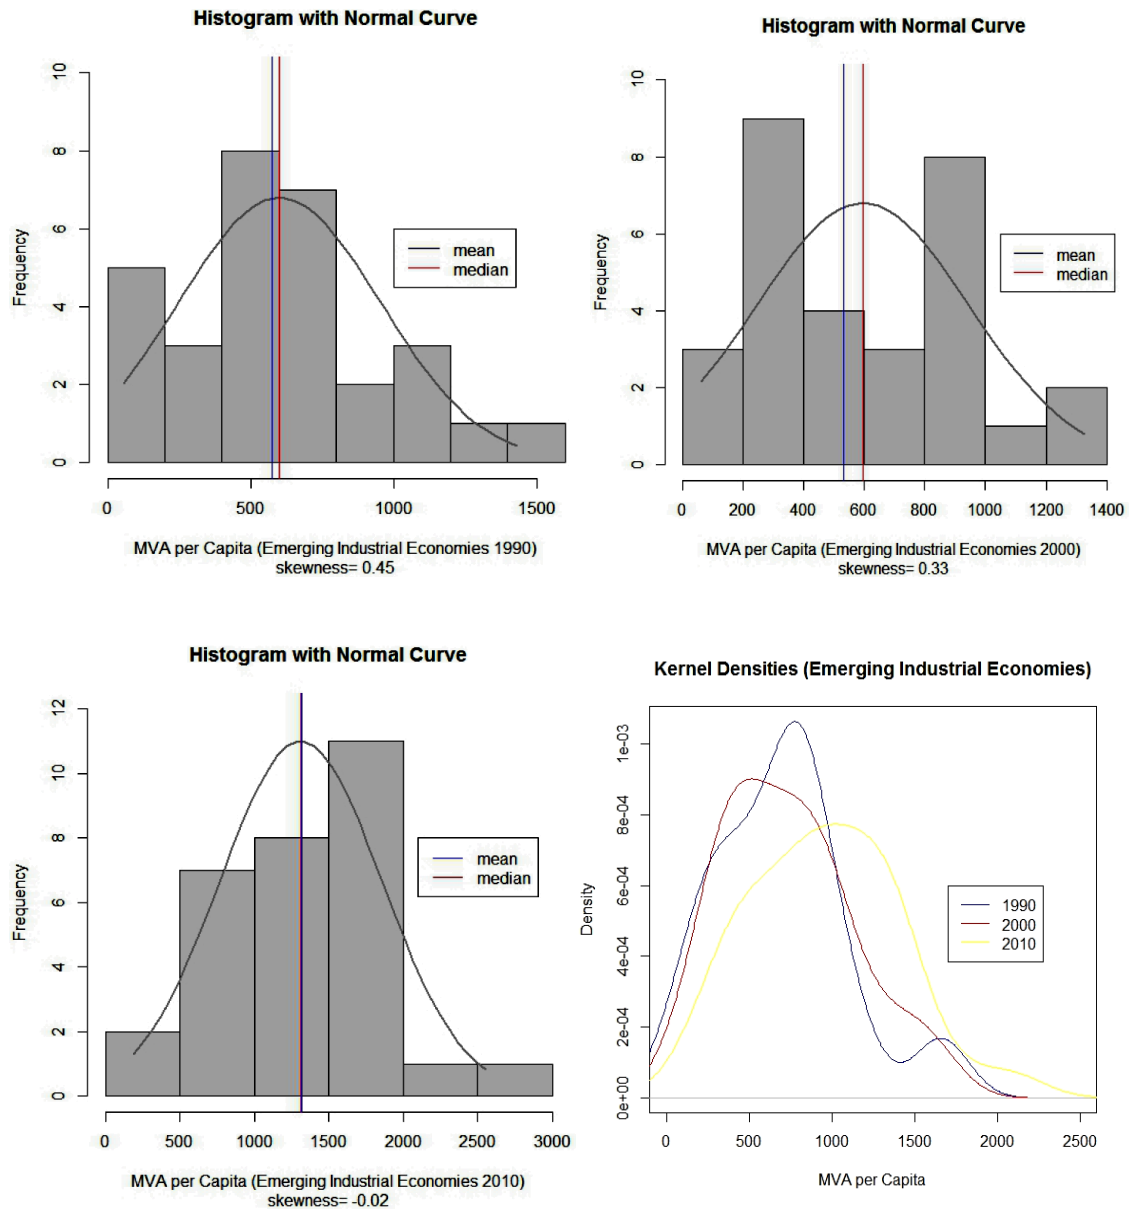

### ***Emerging industrial economies***

The distribution of MVA per capita within the group of emerging industrial economies is expected to be more diverse. To reduce skewness and the effect of outliers, some countries with

a very large MVA per capita were excluded from the analysis and are not included in the histograms of MVA per capita. Figure 7 illustrates the distribution of MVA per capita over the three data points considered.

**Figure 7** Distribution of MVA per capita in emerging industrial economies (EIEs)

(To reflect the main body of the distribution, some outliers are omitted)

Source: UNIDO Statistics, 2013

There is no major difference between the mean and median values in the histograms of share of MVA per capita for emerging industrial economies (EIEs). This implies that the distribution is not significantly skewed after excluding a few outliers. Rather, the distribution seems more

homogeneous and declined from 0.45 in 1990 to -0.02 in 2010. In 2010, the number of EIEs' with an MVA per capita of less than USD 500 decreased significantly and the shift towards further industrialization is visible. Most countries had an MVA per capita of between USD 500 and USD 2,000. Finally, due to the atypical large value, the histogram for 2010 is slightly skewed to the left, or negatively skewed, demonstrating a tendency of increasing MVA per capita in the majority of the countries. Based on the shape of the histograms, it seems that the best distribution fitting the data would be a lognormal distribution (this assertion was statistically tested and confirmed).

Taking a look at the graphs of kernel density estimates, as time passes (see Figure 7), density spreads and the distribution comes closer to a bell-shaped normal density function for the year 2010. This pattern observed over the three data points considered gives weight to the idea to cluster those countries within the same country group and to identify them as emerging industrial economies. Those countries driving this pattern can immediately be identified in Table A5.

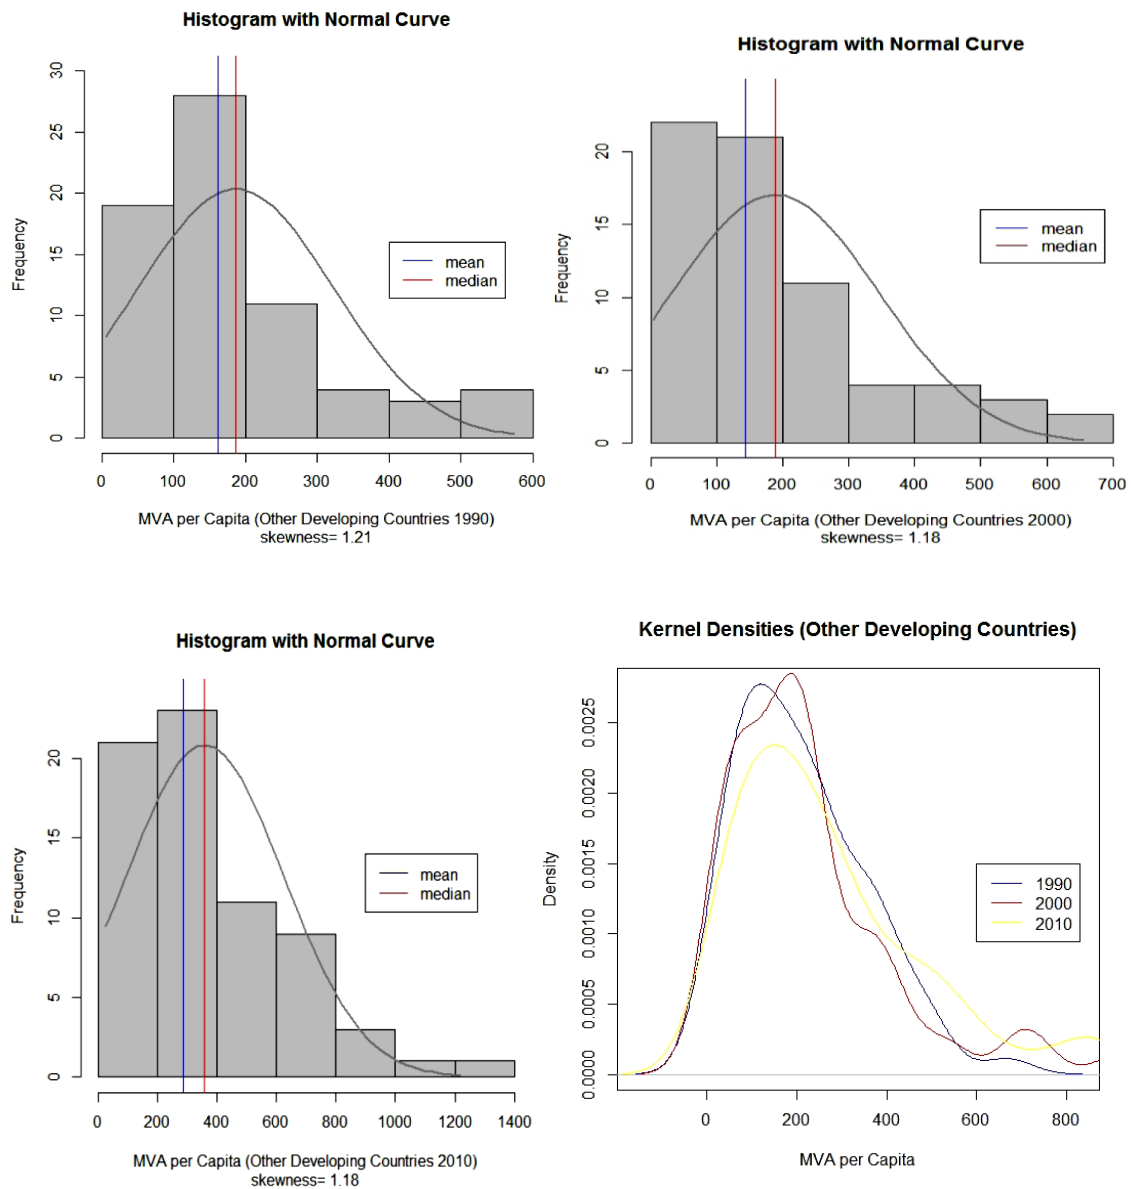

#### *Other developing countries*

As for the distribution of MVA per capita within the group of other developing countries, we can expect that the level of industrialization is also not normal. To decrease the skewness and effect of outliers, some countries were not considered. Figure 8 illustrates the distribution of MVA per capita over the three data points examined.

The histograms for other developing countries reveal almost the same pattern for 1990, 2000 and 2010 with a skewness which remains almost the same. Most countries in this group had an MVA per capita of less than USD 200 in 1990 and 2000, and by 2010, most countries had an MVA per capita of less than USD 400. However, the increasing spread of MVA per capita in 2010 shows that in retaining the growth of manufacturing, some countries have the potential to move to the EIE country group. Two fundamental trends within this group, as highlighted as well by the countries' individual changes in MVA per capita over the period, are manifest. Firstly, there is an increasing spread of values over calendar time. Secondly, even if a few countries seem to have entered sustained manufacturing trajectories, the great majority seem to struggle to maintain a sustained path over a long period. Those countries driving this pattern can be immediately identified in Table A5.

#### **Figure 8 Distribution of MVA per capita in other developing countries (ODCs)**

(To reflect the main body of the distribution, some outliers are omitted)

### ***Least developed countries***

The histograms for the distribution of MVA per capita for LDCs are shown in Figure 9 (again disregarding certain outliers). As expected, there is a huge skewness in the frequency distribution of the share of MVA per capita in the group of least developed countries, which also tended to significantly increase over the second decade. The mean and median values differed significantly and remained that way over the two decades. The range is rather spread and the values are not uniformly distributed.

**Figure 9 Distribution of MVA per capita in least developed countries (LDCs)**

(To reflect the main body of the distribution, some outliers are omitted)

Source: UNIDO Statistics, 2013

Based on the kernel density graph, the distribution is arguably a mixture of two distributions. This means that this group of countries can be divided into two sub-groups such that each subset has its own distribution function, which would better represent the characteristics of the countries in it. The suggested approach could be a useful method to further investigate the properties of the distribution of industrialization in developing countries.

What the above findings imply is that there are certain countries within the group of least developed countries which had (and maintained) a much greater share of MVA in all three

decades examined. This suggests that there are continuously some least developed countries that benefit from higher levels of industrialization, but still not high enough to allow them to climb the manufacturing ladder, while others experience very low levels of industrialization. In comparison to other country groups, LDCs show very slow movement towards becoming more industrialized. In all three decades, more than 50 percent of all least developed countries had MVA values below USD 40. Least developed countries' individual performance over time is presented in Table A5.

## **5 The Effect of the 2008-2009 financial crisis on world manufacturing**

As the first signs of a crisis became apparent in the financial markets in the U.S. in 2007, it was not immediately clear whether this condition would spread to the rest of the world and, if so, to what extent. However, already in 2008, it became evident that the financial crisis had been 'exported' outside U.S. borders, as some of the world's leading economies began to suffer significant losses. Although the crisis originated in the financial markets, it had a negative impact on the economy as a whole. It adversely affected the growth of gross domestic product (GDP) and manufacturing value added (MVA).

While most of the political and economic debates have concentrated on different types of rescue packages aimed at minimizing the consequences of the financial crisis (O'Sullivan et al., 2013), less attention has been paid on determining the losses in the world economy as a result of the financial crisis. This section attempts to estimate the loss of world manufacturing output on account of the financial crisis based on statistics available in the UNIDO MVA database. In general, the effect of the financial crisis on the world economy has been mixed. While it caused a severe decline in the manufacturing production of industrialized countries in the last two years, the effect on developing countries differed to some extent, where a positive (albeit slowed) growth of MVA could be observed.

In the statistical analysis conducted to estimate the losses in manufacturing during the peak of the crisis period (from 2008 to 2010), three different scenarios were considered:

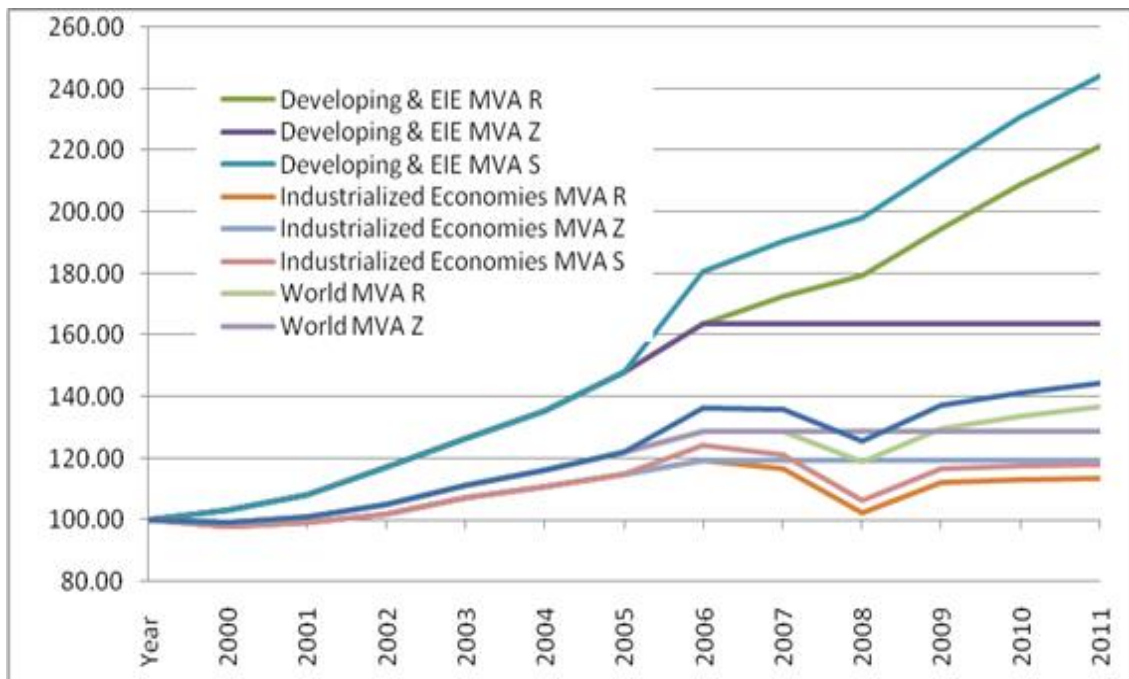

1. Estimated actual MVA;
2. Estimated MVA, assuming zero growth from 2008 to 2010; and
3. Estimated MVA, based on sustained growth.

The sustained growth rate here represents the *status quo ante*, which is the average annual growth rate achieved in the pre-crisis period between 2000 to 2007. All estimates are given at

constant USD 2,000. Growth trends for both country groups in all three scenarios are presented in Figure 10.

The sustained MVA growth rates seem to be higher than the actual growth of both industrialized and developing and emerging industrial economies in 2008-2010. During this period, neither developing nor industrialized countries were able to reach this level. However, once the zero growth scenario is included in the analysis, we observe that developing countries surpassed zero growth, thereby indicating continuous growth of MVA (nevertheless, at a somewhat slower pace than if sustained growth had been reached), while industrialized countries fell short even in this scenario, indicating that they experienced real negative growth of the manufacturing sector during the crisis period.

**Figure 10** Real, zero and sustained growth of MVA

Source: UNIDO Statistics, 2013

Estimates have been produced not only for trends, but also for the amount of combined losses of manufacturing output in 2008-2010 (see Table 4).

**Table 4 Estimated amount of losses of MVA from 2008 to 2010**

Country group	<i>Scenarios</i>	
	Zero growth	Sustained growth
Developing & EIE	785.5	-798.3
Industrialized economies	1,399.7	-685.4
World	614.3	-1405.1

*Source:* UNIDO estimates based on MVA data, in billion USD.

The total loss of manufacturing output in the years 2008-2010 under the zero growth assumption, that is, if no financial crisis had occurred and industrial production had remained at the level of 2008, was estimated at USD 361 billion. Under this assumption, developing countries suffered no loss; however, under the same assumption, the loss of MVA in industrialized countries was around USD 670 billion. In comparison to sustained growth rates before the crisis, the loss of MVA in 2008-2009 was estimated at USD 875 billion at 2000 constant prices, which would be more than USD 1 trillion at current prices.

However, it is difficult to determine how much of this loss was triggered by the financial crisis and how much of it was attributable to other factors. On account of their relatively high growth rate, developing countries have significantly increased their share in world industrial output. According to UNIDO estimates (see Table A2, A3 and A4 in the appendix), contributions of developing countries and EIEs to world MVA increased from less than one-fifth in 1990 to almost one-third in 2010. The manufacturing sector in these countries has been the major driving force behind increasing economic growth, and their contribution to GDP jumped on average from 16 percent to 20 percent within two decades. Increasingly over the last decade, MVA grew quite rapidly in larger developing economies. In terms of volume of worldwide manufacturing output, China placed second, right behind the U.S., overtaking countries like Japan and Germany, while in 2009, India became one of the top 10 producers. While the share of MVA has been rising in developing countries, the trend was quite the opposite in industrialized countries. Due to massive outsourcing and transfer of production plants to developing countries, the share of manufacturing has steadily fallen in industrialized countries. The gap has been filled by the increased share of the services sector. For example, finance, real estate and business services make up one-fourth of the economy in the euro zone and almost one third in the U.S. (see Figure 11).

**Figure 11 Share of manufacturing and financial and business services in GDP in industrialized countries from 2004-2011, at current USD**

Source: US Bureau of Economic Analysis, Eurostat

Some economists interpret the current share of financial and business services in industrialized economies as being dangerously high, because it is supposed to play a supporting, not a leading role in the economy. When financial and business service industries assume a dominant role, a minor financial disorder may trigger a major economic fallout. These industries occupy a much lower share in developing countries, including China and India, which might have saved them this time from falling into an economic recession as a result of the financial crisis. However, a lack of sufficient financial services has also been a barrier to investment in production in many developing countries.

Hence, although it is evident that global manufacturing has been undergoing a profound transformation even before the onset of the financial crisis, a number of structural impacts can be identified by analysing countries' individual trends over the five-year crisis period from 2007 to 2012. Figure 12 presents a selection of 'winners' that showed the most striking positive trends in MVA per capita and the negative performances of the 'losers'. Among those countries that were able to grow during the five-year crisis period from 2007 to 2012, China is by far the outlier. On account of its increase in MVA per capita of 56 percent, China increased its share of world manufacturing value added by nearly 6 percent within five years only. The other giant, India, experienced a growth of MVA per capita of nearly 30 percent, while other best performers from South-East Asia, namely Viet Nam and Bangladesh, registered increases in MVA per capita of over 30 percent. The only European country that managed to record sustained positive results was Poland, while among the major industrialized countries only the Republic of Korea entered the top 25 ranking with an increase of MVA per capita of 22 percent.

As shown in Table A6, all other leading manufacturing economies witnessed a contraction of their MVA per capita, from nearly 6 percent in the U.S. to the dramatic 25 percent in Italy (followed by -24 percent in Spain and -17 percent in both United Kingdom, and Canada and -14 percent in Finland). All other major industrial economies like Germany, Japan and France were able to contain their losses below 10 percent, while relatively smaller sophisticated economies like Ireland, Israel, Singapore and Taiwan registered modest increases in MVA per capita of around 5 percent.

As shown in Figure 12, we mainly find emerging industrial economies (6 countries) among the top 25 winners, the remaining being equally distributed between other developing countries (9) and least developed countries (9). On the contrary, the group of losers includes 9 industrialized economies, 9 countries of the ODC group, only 2 LDCs and, finally, 5 minor emerging industrial economies. Among the other key EIEs (see Table A6), Turkey, Thailand, Indonesia and Argentina increased their MVA per capita between 12 percent and 20 percent, while Malaysia, Mexico, Brazil, the Russian Federation and South Africa contained their losses or displayed relatively slow growth rates of MVA per capita.

To sum up, the five-year crisis had mixed effects, with few EIEs capturing global manufacturing opportunities and traditional industrialized economies witnessing their resilience being compromised by the long contraction of internal demand and increasing competition in international markets.

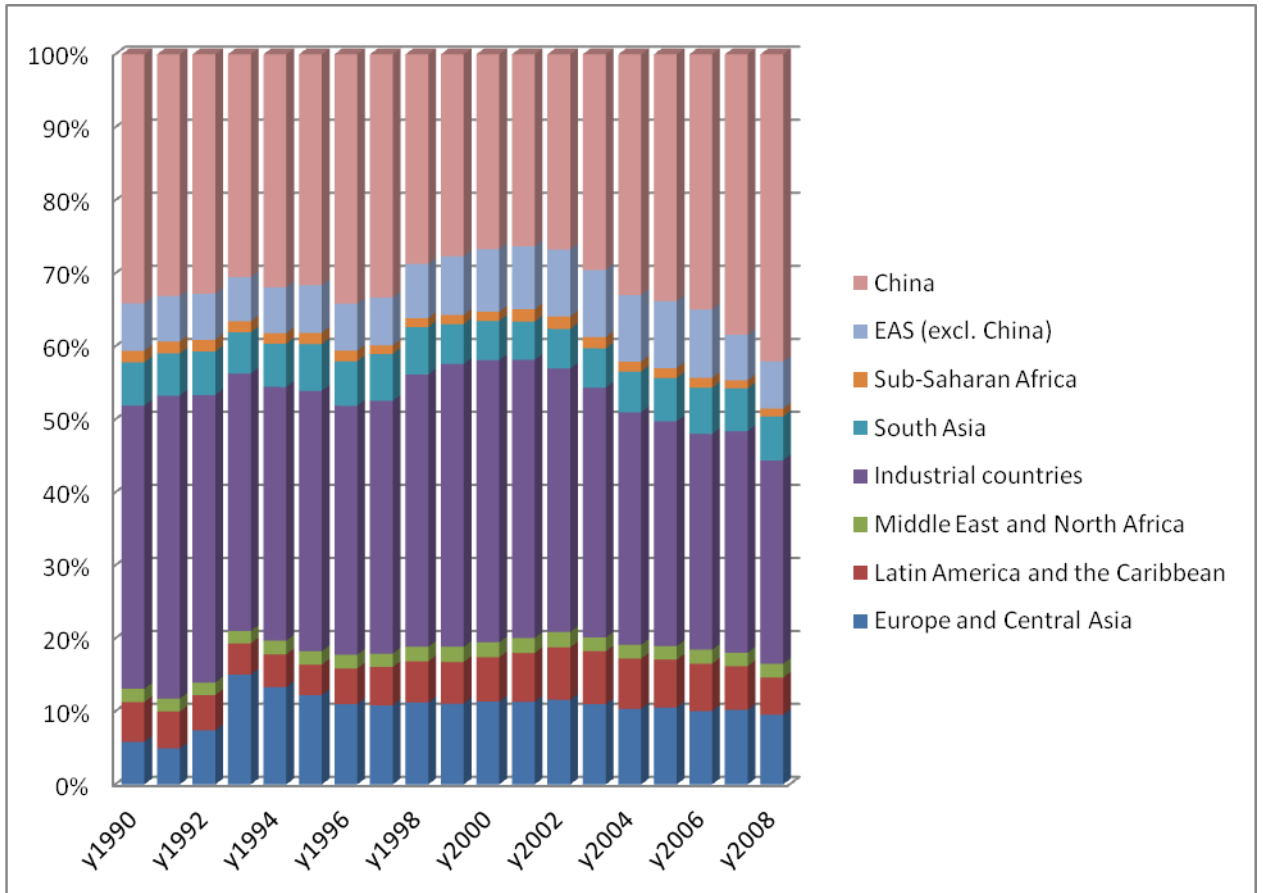

## **6 The impact of MVA redistribution on other variables**

The profound changes in the global distribution of manufacturing described above began in the 1990s, developed over the following decade and were accelerated by the structural break introduced in the data by the financial crisis and its long wave-impact over the period between 2007 and 2012. As a result, given the pervasive impact of manufacturing trends on the rest of the economy in each country (and region), we can explore several causal chains and correlations with other variables such as GDP per capita or employment levels in manufacturing.

**Figure 12 The effect of the financial crisis: Winners and losers, 2007 – 2012**

**Figure 13** Share of manufacturing employment by region, separating China

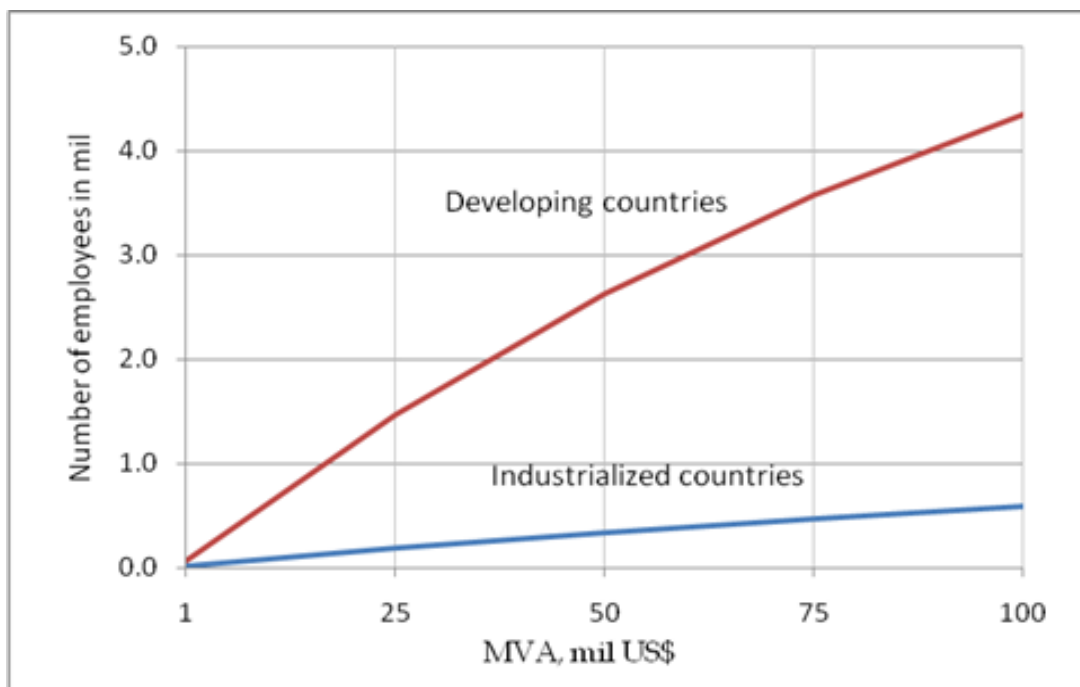

Source: UNIDO Statistics, 2013

With regard to the changes in GDP per capita, Tables A2, A3 and A4 in the appendix present GDP and GDP per capita levels as well as shares of world GDP for each country considered. The strong correlations between MVA and GDP have already been discussed in previous sections. In 1990, world GDP per capita was around USD 5,700 (the MVA per capita being equal to USD 941), with industrialized countries registering a GDP per capita that was almost 19 times higher than that in developing countries and EIEs (their MVA per capita was also 19 times higher). In 2010, world GDP per capita was around USD 7,400 (MVA per capita being equal to USD 1,240). However, the gap between industrialized countries and the rest of the world was drastically reduced: GDP per capita was 13 times higher in industrialized countries, while differences in MVA per capita dropped drastically by half, from 19 times to 10 times higher in industrialized economies. As a result of this dramatic shift driven mainly by emerging industrial economies concentrated in a few regions, the share of manufacturing employment across region and country groups changed significantly (see Figure 13). For example, from 1990 to 2008, China captured nearly 10 percent of world manufacturing employment.

By the end of the period considered above, the economic crisis had caused job losses in manufacturing throughout the world. Due to the drop in demand, manufacturing firms were forced to reduce delivery, cut entire production lines or close factories altogether. Production decline was more significant in industrialized countries, however, its impact on job losses was severe in developing countries. This phenomenon was not always adequately reflected in official statistics (ILO, 2012). Developing countries suffered two forms of setbacks in their labour and income situation due to the external and internal effects of the economic crisis.

The external effect relates to the transmission of the recession from industrialized countries to developing countries through remittances. A large number of migrant workers from developing countries are employed in industrialized countries. During the crisis period, these workers were generally more vulnerable than resident workers to job loss due to the informal nature of their jobs and, often, their insufficiently protected labour contracts. The loss of jobs in recipient countries (industrialized) adds to the unemployed labour force in the country of origin (developing).

**Figure 14** MVA in the scale of number of employees

Source: UNIDO estimates based on MVA and INDSTAT databases

The internal effects of the crisis are related to the labour-intensive nature and relatively lower labour productivity of industrial production in developing countries. For the production of the same amount of industrial products, the number of persons employed in developing countries is relatively higher (the labour/capital ratio is higher than in industrialized economies where the

labour force is substituted by capital investments). Subsequently, the loss of the same amount of manufacturing production in the case of developing countries is likely to correspond to more losses of manufacturing jobs than in industrialized countries. This pattern is documented in data produced by UNIDO in MVA and INDSTAT2 databases.

Overall labour productivity of any given economy can be proxied by MVA per employee. This relationship can also provide a rough estimation of the expected number of employees required to produce the given amount of MVA at the different levels of productivity. A calculation made from a sample of industrialized and developing countries has shown that production of MVA equivalent to USD 1 million requires 7.7 employees in industrialized countries, but only 66.7 employees in developing countries. However, the number of required employees tends to diminish as production grows. The relationship between MVA and number of employees is presented below based on these assumptions.

To sum up, Figure 14 shows how the production of the same amount of MVA requires a number of employees in developing countries that is higher than in industrialized countries. On the other hand, this implies that a reduction of industrial production by the same amount will trigger relatively higher job losses in developing countries than in industrialized countries. This is why the number of job losses in the manufacturing sector of industrialized countries was similar to those in developing countries and EIEs, although the former experienced the most drastic contraction of MVA. Based on the methodology provided above, it was estimated that of the 10 million job losses in manufacturing as a result of the financial crisis, half occurred in developing countries.

## **7 Conclusion**

Global manufacturing has changed dramatically over the last two decades, the financial crisis being the apex of this transformation. The present report builds on the MVA dataset from 1990 to 2013 published by UNIDO in the *International Yearbooks of Industrial Statistics*. The analysis of manufacturing trends developed in this report for almost 200 countries over the last two decades has revealed some distinct patterns in global manufacturing. Firstly, manufacturing still matters for a large number of countries across the world. The positive relationship linking manufacturing value added per capita and gross domestic product per capita for different country groups demonstrates that industrial transformation remains the main engine of economic growth. From 1990 to 2010, the gap between industrialized countries and the rest of the world in terms of MVA per capita reduced by half, from a 1 over 20 ratio to a 1 over 10 ratio. Emerging industrial economies managed to climb the manufacturing ladder and unsettling

traditional industrialized economies. Secondly, the process of redistribution of manufacturing value added across different countries and within different country groups over the period considered has been significant, especially among industrialized countries and EIEs. The report also highlights the prevalence of highly unequal distribution of MVA among countries.

Despite the diminishing share of industrialized countries, redistribution is largely taking place at the upper segment of country groups. The emerging industrial economies are gaining higher shares in global industrial production, but the countries at the bottom are stuck in stagnation. Close to 50 countries of the LDC group, which represent around 13 percent of the world population, produce less than 0.5 percent of global industrial production.

Finally, the report presented a unique investigation of the manufacturing losses caused by the global financial crisis across different countries and country groups. The report also presented original estimates of manufacturing losses as well as of the impact of the redistribution of manufacturing on other related variables, namely GDP and manufacturing employment.
